

Cloud Computing: The Optical Perspective

Paweł Brzozowski
Control Plane R&D
June 2012

Evolution of Cloud Architectures

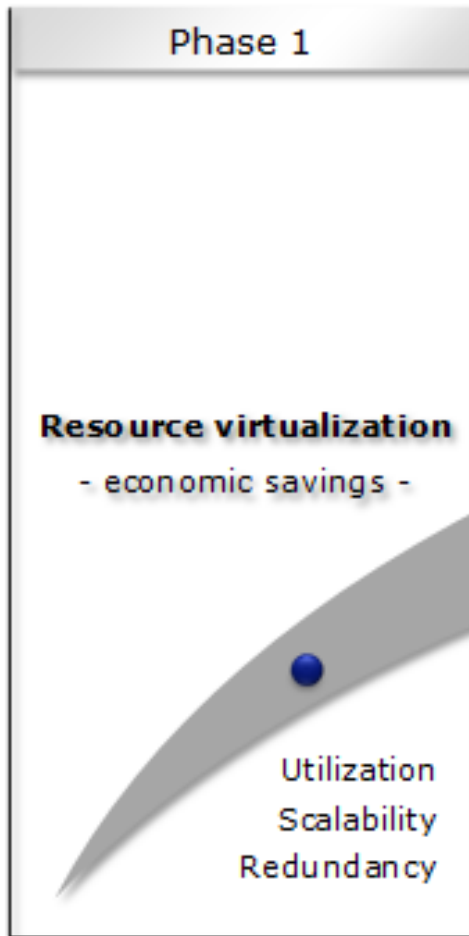

Resource Virtualization

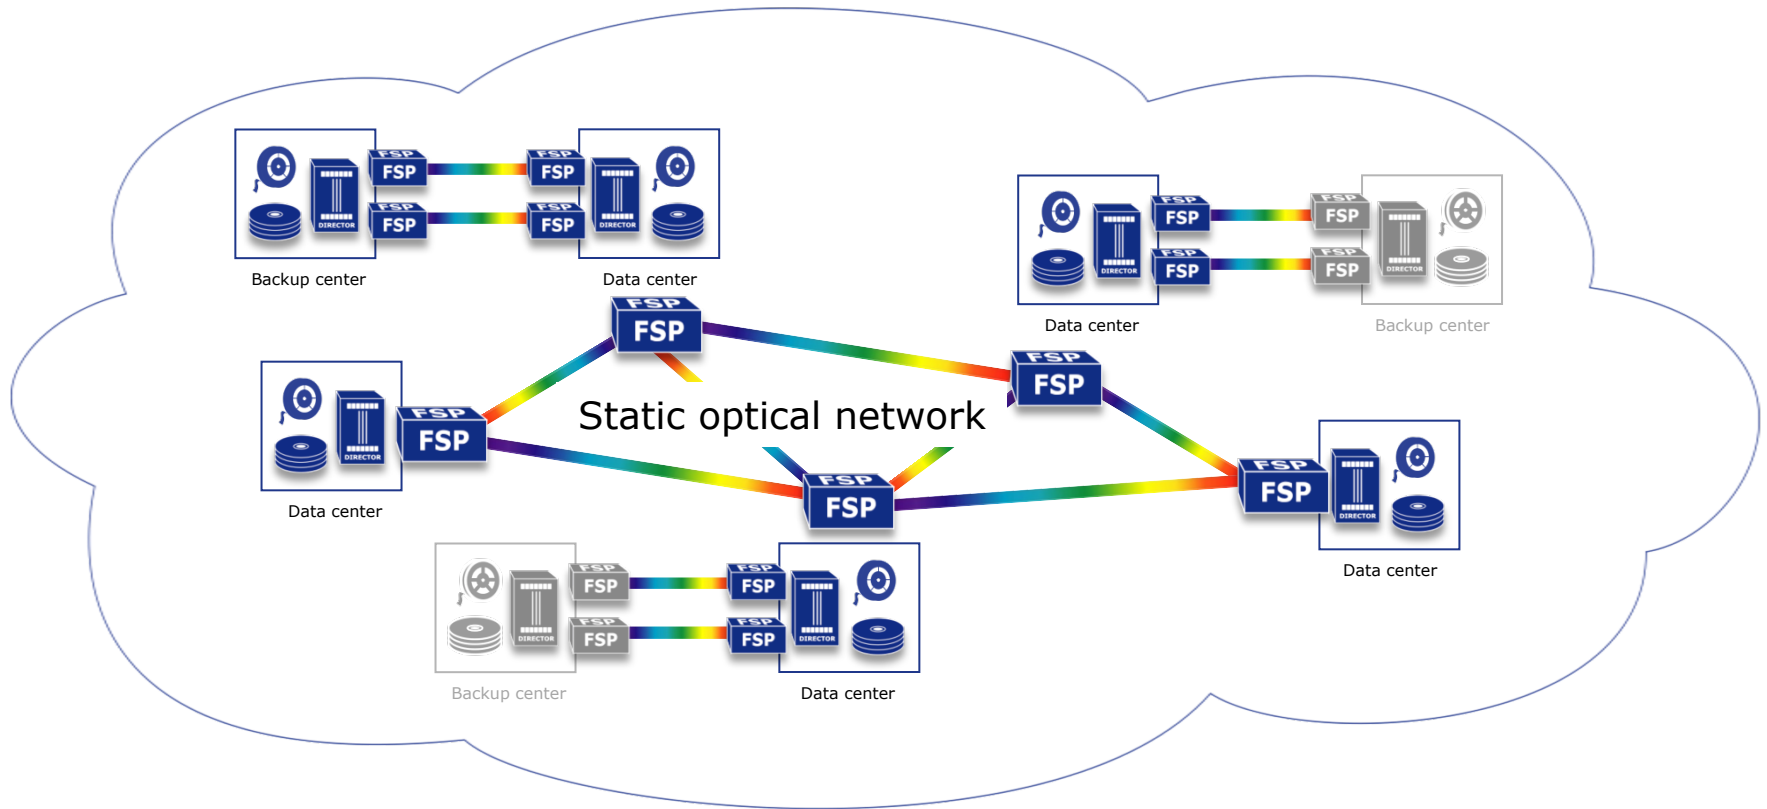

Server and storage clustering for increased efficiency inside the data center

Desired Network Attributes

- > Cheapest bit/s transport
 - > xWDM maximizes fiber throughput
- > Protocol flexibility
 - > Interfaces ranging from 10Mbit/s to 100Gbit/s
- > Lowest latency
 - > Transparent wavelength conversion
 - > SAN: Save expensive buffer credits
- > Single-span performance
 - > Up to 200km without mid-span amplification
- > Seamless integration
 - > Full set of SAN equipment vendor qualifications

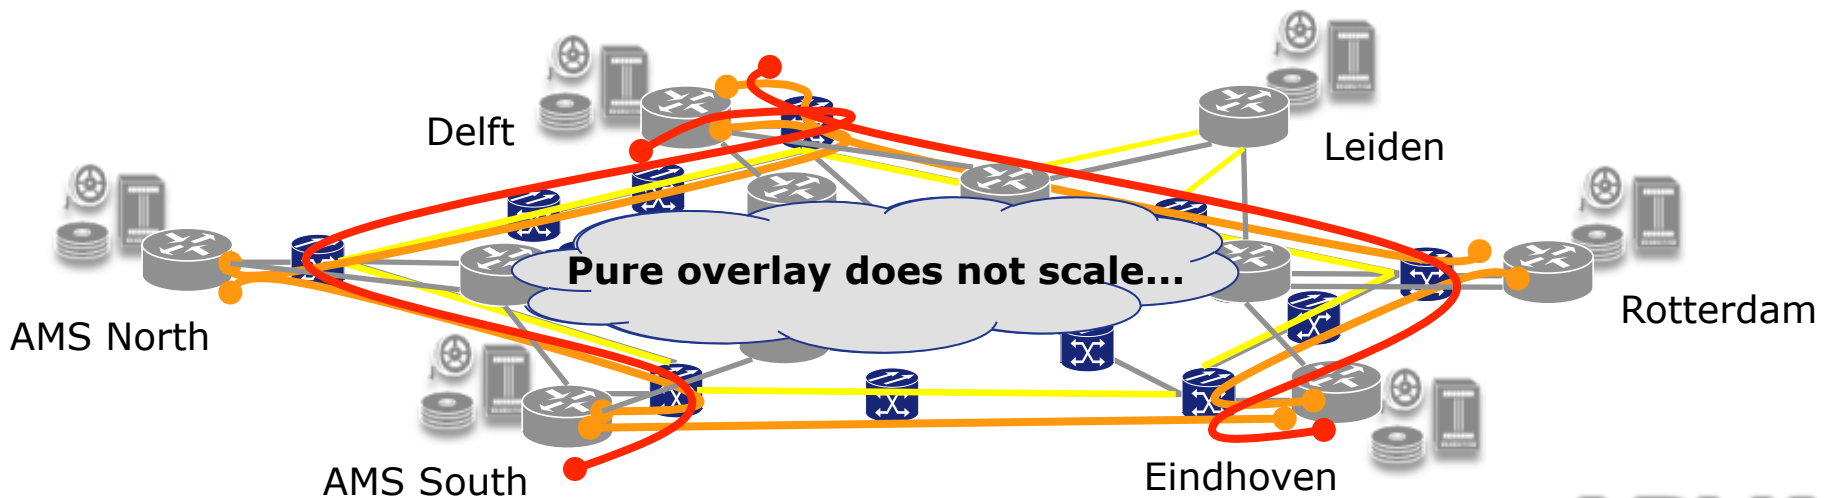

Data Center Virtualization

High-speed inter-connection of cloud facilities for infrastructure flexibility

Data Center Interconnect

- > Data Center Interconnect split into two layers: Packet & Optical
 - > Packet Service Layer (L2/L3 DCI)
 - Various technologies: x-VPLS, OTV, TRILL, IP/MPLS, etc.
 - Provides various services directly to clients
 - Provides infrastructure to Cloud/CDN applications
 - Focus on client functionality (VM live migration support, virtualization, etc.)
 - > Optical Transport Layer (overlay model)
 - WDM transport elements, ROADMs, regenerators, amplifiers
 - Provides point-to-point wavelength services to Packet layer
 - Enables cheap optical bypass for data center transit where needed
 - Focus on cheapest bit/s transport between 2 endpoints

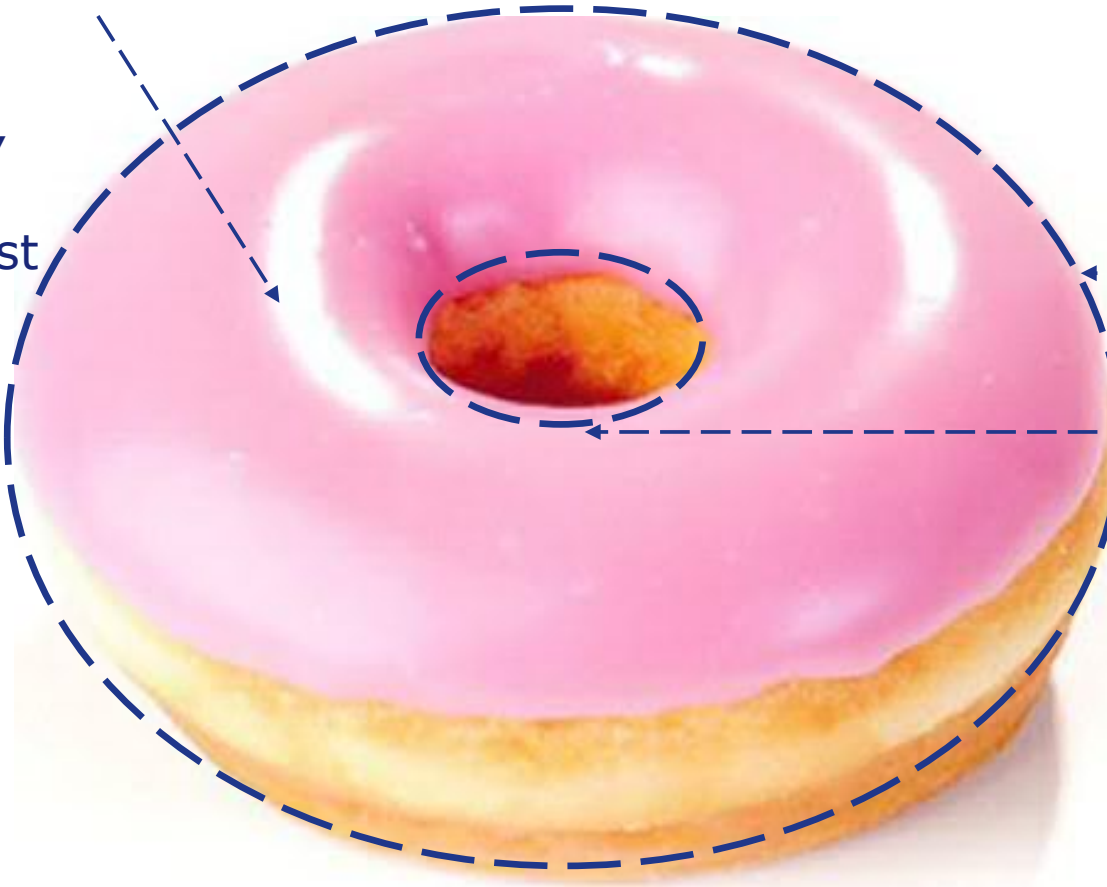

Data Center Interconnect

L2/L3 + overlay VPN integration: The Donut

Optical switching:

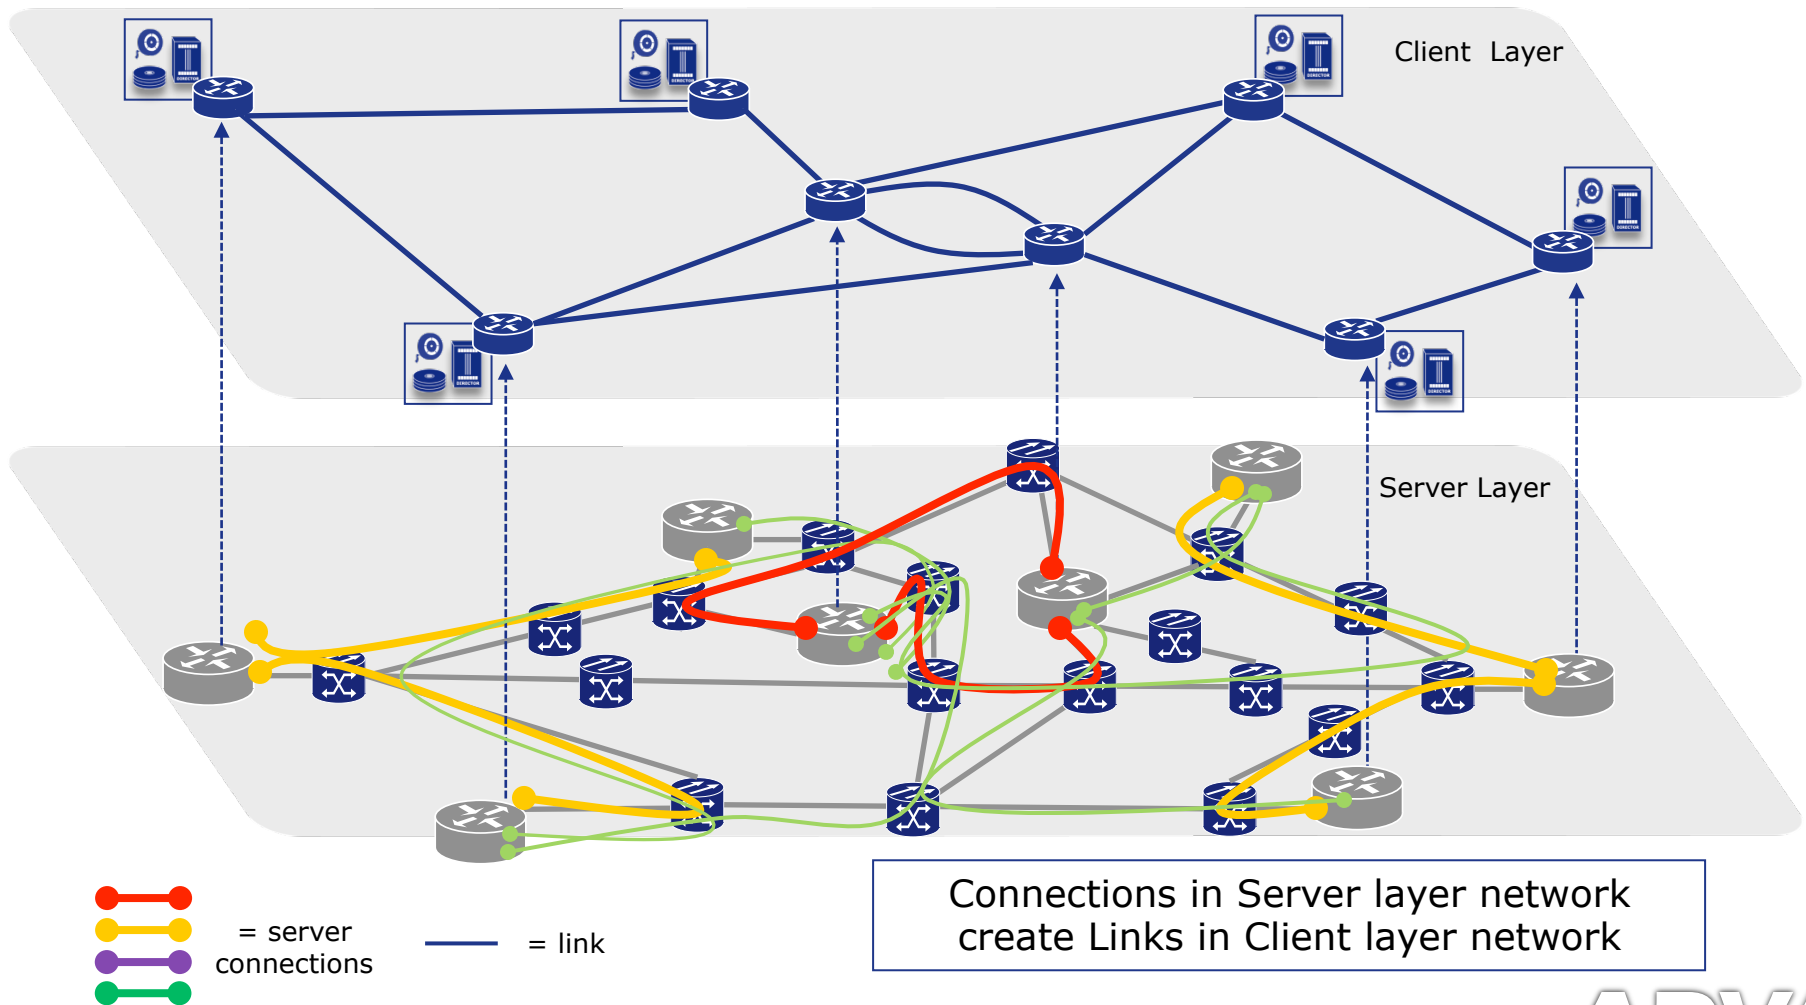

- Donut's „contents“
- Lowest cost for bit/s
- Connects rings

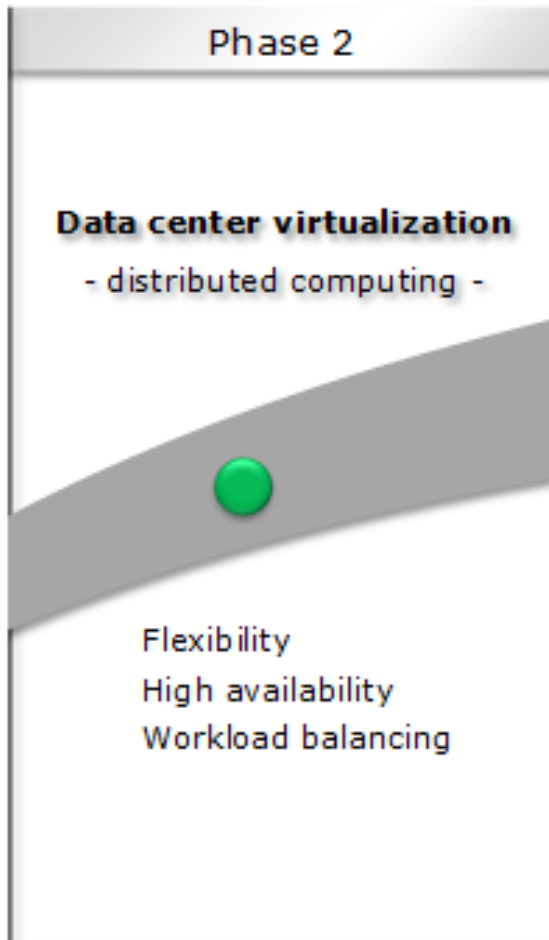

Electrical switching:

- Most flexible
- Outer ring: Data Centers (PE routers)
- Inner ring: Redistribution (P routers)
- Only at the edges

Data Center Interconnect: Traditional Layering Concept

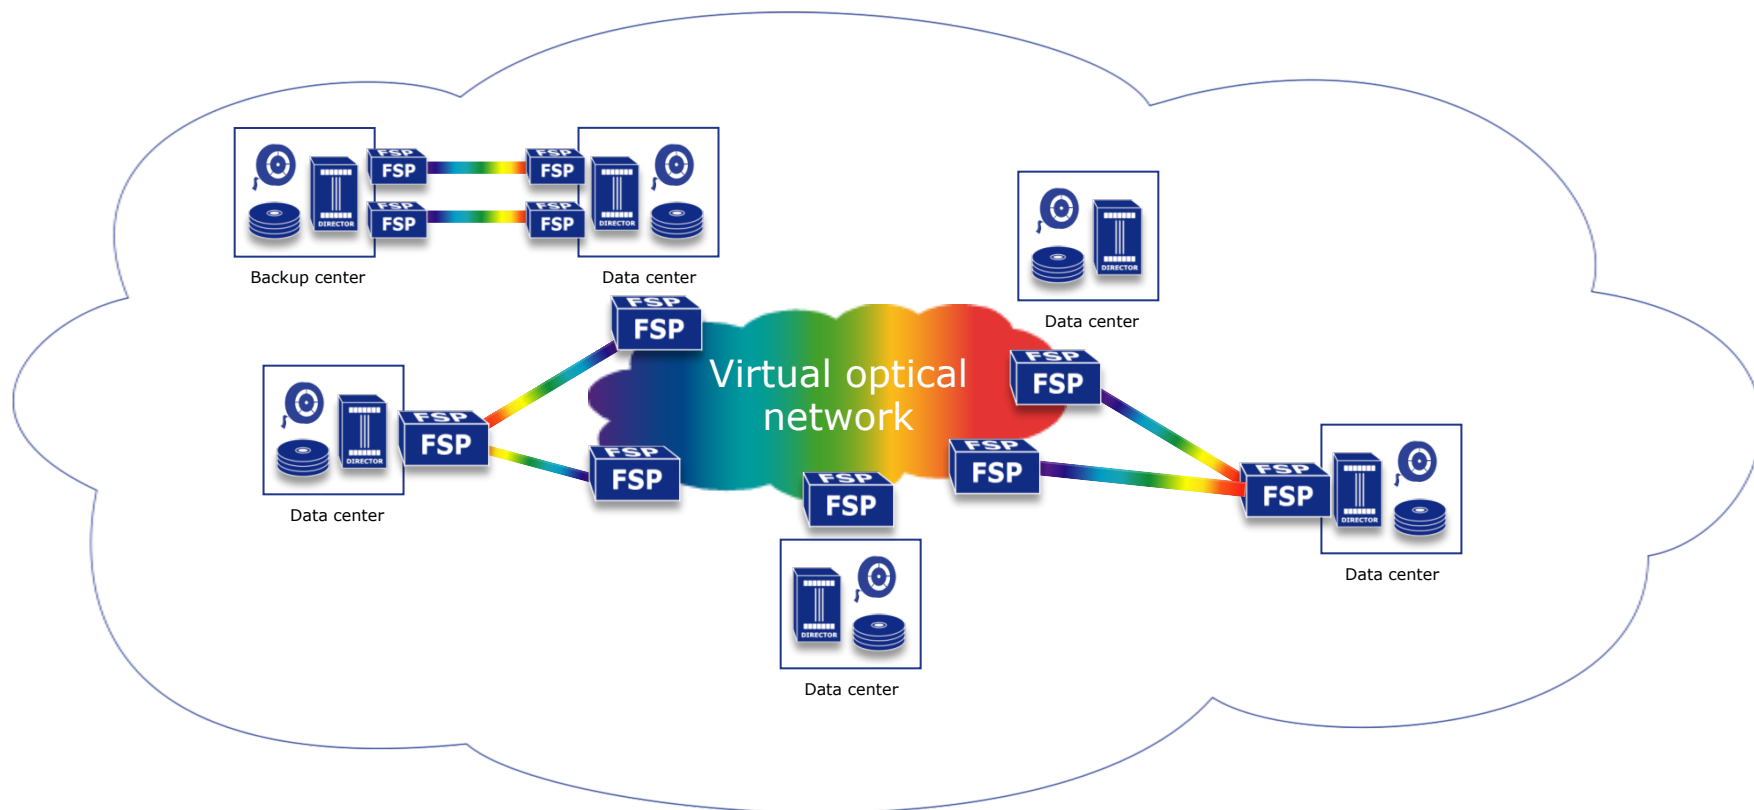

Desired Network Attributes

- > Long reach
 - > 2000km non-regenerated transmission
- > Efficient mesh networking
 - > Multi-degree ROADM implementation
 - > Optical switching cost is negligible
- > Fast provisioning
 - > Tunable optical layer and service management
 - > (optional) Homogenous control plane for service activation
- > Ubiquitous solution
 - > Single platform for all transport applications
- > High availability
 - > 1+1 service protection + restoration (if CP used)
 - > Protects against multiple failures

Network Virtualization

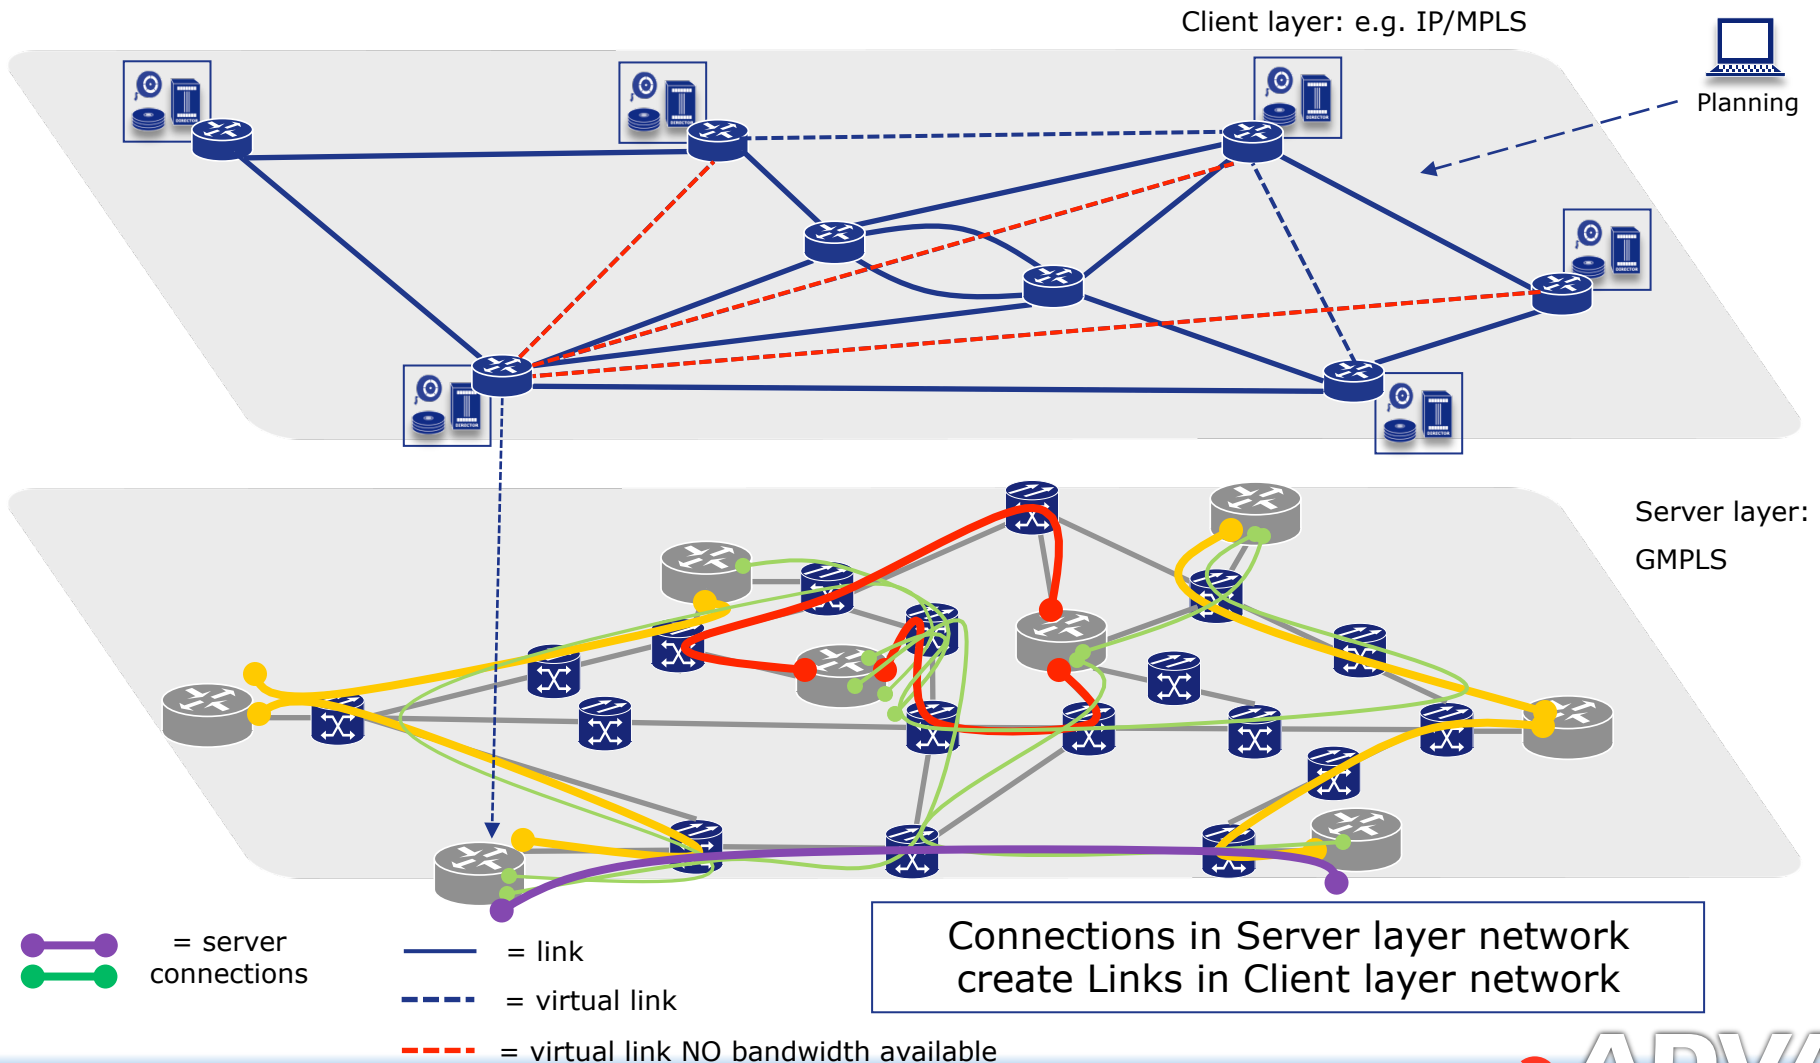

Dynamic network resource allocation for cloud services agility

Virtual Network Topologies

- > Abstract representation of a real network
 - > Built from virtual components – virtual links, virtual nodes
- > Purpose: Abstraction
 - > Represent multiple real components as a single virtual component
 - Example: represent domain A as single virtual node in domain B
- > Purpose: Adaptation
 - > Represent server layer network capabilities in client layer network
 - Example: expose a lambda connection as a link in a packet topology
- > Purpose: Activation
 - > Coordination activation of capabilities across layers, domains
 - Example: server layer connection activated during client layer signaling
- > Virtual Topologies are generally planned
 - > VNTs created during application planning process
 - Prior to service provisioning, ongoing over lifetime of network
 - > Represent "potentialities" of the real network
 - E.g. what real connectivity "can" be, when requested

Data Center Interconnect: Virtual Topology Concept

Virtual Links

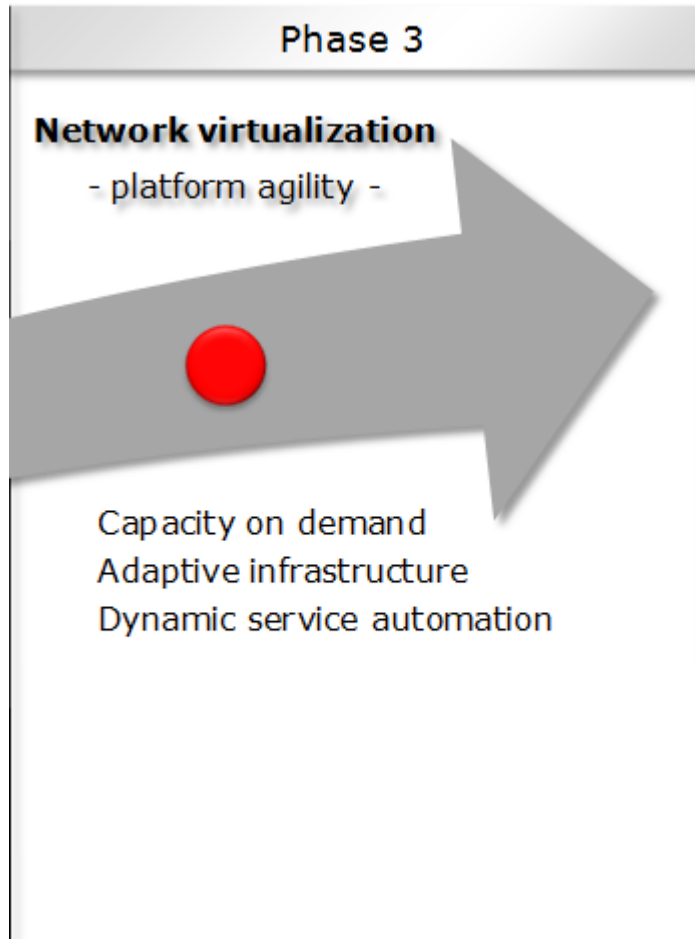

- > Represent "potential" connectivity in a topology
 - > Entered into standard Traffic Engineering databases (TEDB)
 - Standardized TE extensions to regular IGP routing
 - Advertised into client TE routing, standard LSA formats/TLVs
 - Annotated with standard TE attributes (metric, bandwidth, etc)
 - Essentially indistinguishable from normal "real" TE links
 - > Server network resources not committed to virtual link
 - E.g. bandwidth/wavelength not committed until link is used
 - > Made available to path computers in the client network
 - PCE computes paths using links in TEDB, real or virtual
- > When link is used ...
 - > E.g. when signaling in client network traverses a virtual link
 - Server network control plane is activated
 - Server network connections provisioned to commit resources
 - If successful, signaling in client network allowed to proceed
- > Virtual links coordinate information, activation across networks

GMPLS Overlay

- > GMPLS UNI/ENNI
 - > Interoperable service activation across layers and domains
- > Precursor: RFC4208
 - > Defines the overlay network model, concepts
 - > Outlines multiple scenarios, options, mechanisms
 - > Initially issued in 2005, considerable experience since then
- > Update: draft-beeram-ccamp-gmpls-uni-bcp
 - > Presents "best current practice" for utilizing RFC4208
 - > Derived from specific experiences, lessons learned
 - Multi-layer activation, use of virtual topologies
 - Label signaling across technologies
 - Coordinating administrative status
 - Routing updates to support virtual nodes
 - Handling of generic constraints
 - Macro SRLGs, MELGs
 - L1VPNs
- > Alternative: OIF UNI2.0

Desired Network Attributes

- > Fast provisioning
 - > Tunable optical layer and service management
- > Highest capacity
 - > 50GHz grid with up to 100Gbit/s per wavelength
- > Enhanced flexibility
 - > Directionless and colorless optical switching
 - > (optional) gridless optics
 - > 2000km non-regenerated transmission
- > Automated configuration
 - > mature GMPLS control plane implementation
 - > The difference in provisioning time
 - > Further enhances flexibility of the optical network
- > Virtual bandwidth
 - > Inter-layer intergration mechanisms:
e.g GMPLS UNI, OIF UNI
 - > Multi-layer service recovery: SRLGs, MELGs
 - > Virtualization of optics: L1VPNs

Thank you
