#### Abstract

The GLUE specification is an information model for Grid entities described using natural language and enriched with a graphical representation using UML Class Diagrams. As a conceptual model, it is designed to be independent from the concrete data models adopted for its implementation. Rendering to concrete data models such XML Schema, LDAP Schema and SQL are provided in a separate document.

## 1 Introduction

In this document, we present a conceptual information model for Grid entities described using natural language and enriched with a graphical representation using UML Class Diagrams. As a conceptual model, it is designed to be independent from the concrete data models adopted for its implementation. Rendering to concrete data models such XML Schema, LDAP Schema and SQL are provided in a separate document. From the semantic viewpoint, the concrete data models should represent the same concepts and relationships of the conceptual information model; nevertheless they MAY contain simplifications targeted at improving query performance or other aspects of interest.

This information model is based on the experience of several modeling approaches being used in current production Grid infrastructures (e.g., GLUE Schema 1.x [glue-1.x], NorduGrid schema [ng-schema], Naregi model [naregi-schema]). The main supporting use cases are collected in the use cases document [glue-usecases].

The mapping to concrete data models is defined in a separated document [glue-real] (new mappings MAY appear in the future). Profile documents SHOULD appear to define how to generate and use the information in production scenarios (e.g., a profile MAY decide that an attribute which is optional in the conceptual model, is considered mandatory in a certain Grid infrastructure; or that optional attributes are never published).

## 2 Notational Conventions

The key words “MUST”, “MUST NOT”, “REQUIRED”, “SHALL”, “SHALL NOT”, “SHOULD”, “SHOULD NOT”, “RECOMMENDED”, “MAY”, and “OPTIONAL” are to be interpreted as described in RFC 2119 (see <http://www.ietf.org/rfc/rfc2119.txt>).

## 3 General Statements

The Information Model and its renderings **MUST** be considered case-sensitive. Each GLUE entity **MUST** have an ID attribute (except is made for the Extension class). Every ID MUST be a URI. As a general guideline, ID's SHOULD be persistent at least for a day when assigned to an entity. It is needed for recognition or for access to the characteristics of the related entity over time and across different information sources. The ID MUST NOT be interpreted by the user or the system as having any meaning other than an identifier. In particular, there is no relationship between an ID and a network endpoint. All ID attribute values MUST be valid URIs. The usage of URN (Uniform Resource Name, a subset of Uniform Resource Identifier or URI) is RECOMMENDED. The motivations for choosing URI's reside in the fact that Grid services are evolving towards Web-based technologies such as Web Services, therefore it is RECOMMENDED to adopt the same identification system.

As regards unit of measure, multiple of bytes **MUST** refer to the SI (*Le Système International d'Unités*) prefix ([http://en.wikipedia.org/wiki/SI\\_prefix](http://en.wikipedia.org/wiki/SI_prefix)), therefore GB is 10<sup>9</sup> Bytes and not 2<sup>30</sup> Bytes (the latter are GibiBytes).

In Appendix A, we provide guidelines for place-holder values that MUST be used when the attributes have no good default value or when the attribute cannot be measured for some reason.

As regards the extensibility, two main approaches are introduced to extend the information associated to the existing classes: the OtherInfo attribute and the Extension class. The OtherInfo attribute is present in several classes, its type is string and its multiplicity is \*. This SHOULD be used for associating a flat list of tags to a certain class instance.

The Extension class is associated to the Entity class (therefore also to all the derived classes) and enables to link key,value pairs to any GLUE class instance. This SHOULD be used when there is the need for advertising more structured information, for instance an attribute not present in the model with the related value.

Both solutions are proposed because they have a different impact in the implementations: the OtherInfo approach is easier to query, nevertheless it MAY require parsing in case of concatenation of different chunks of information (e.g., attribute name and attribute value). The Extension class offers a two-dimensional construct, nevertheless it is more complex to query.

The extensibility regarding the addition of new classes and associations is not supported at the conceptual level. We RECOMMEND to create specialization of the conceptual model and to implement them by extending the concrete data models. Such extensions MUST NOT be considered part of the GLUE specification, nevertheless we RECOMMEND submitting them to the GLUE WG for consideration."

#### 4 Template

In order to enrich the UML Class Diagrams with additional information, a table for each UML class is provided. The descriptive table is composed by three parts.

The first part refers to the whole entity and presents the entity name, the entity from which it inherits and the description of what the entity is.

The second part refers to the properties of the class; for each of them, the following characteristics are described: the attribute name, the data type, the multiplicity concerning how many values are allowed (\* means zero or more), the unit of measurement and a description. For easy of reading, the properties that are inherited from a parent class are also listed. As regards the multiplicity, the value of zero means that it is allowed to refrain from publishing a value for the related attribute even though this MAY be measured.

The third part refers to the associations (association, composition, aggregation or association class) that the class MAY hold with other classes. For each association, the associated class endpoint is described in terms of the associated end class and key attribute, the multiplicity (i.e., the number of instances of the associated class that are allowed) and a description. The inherited associations are also reported in the "inherited association end" if they are not redefined in the "association end". The template structure is the following:

| Entity                     | Inherits from |       |      | Description |
|----------------------------|---------------|-------|------|-------------|
| Inherited <u>Attribute</u> | Type          | Mult. | Unit | Description |
| <u>Attribute</u>           | Type          | Mult. | Unit | Description |
| Association End            |               |       |      | Description |
| Inherited Association End  |               | Mult. |      | Description |

**Deleted:** In Appendix 16, we provide guidelines for place-holder values that MUST be used when the attributes have no good default value or when the information provider is unable to obtain a dynamic value.¶

**Deleted:** The terms "attribute" and "property" MUST be considered synonyms in the scope of this document.¶

## 5 Conceptual Model of the Main Entities

This section introduces the main entities of the GLUE information model. They capture the core concepts relevant in a Grid environment. The main entities SHOULD be used to derive specialized information models. In Figure 1, the classes and the related relationships are presented in the form of a UML Class Diagram.

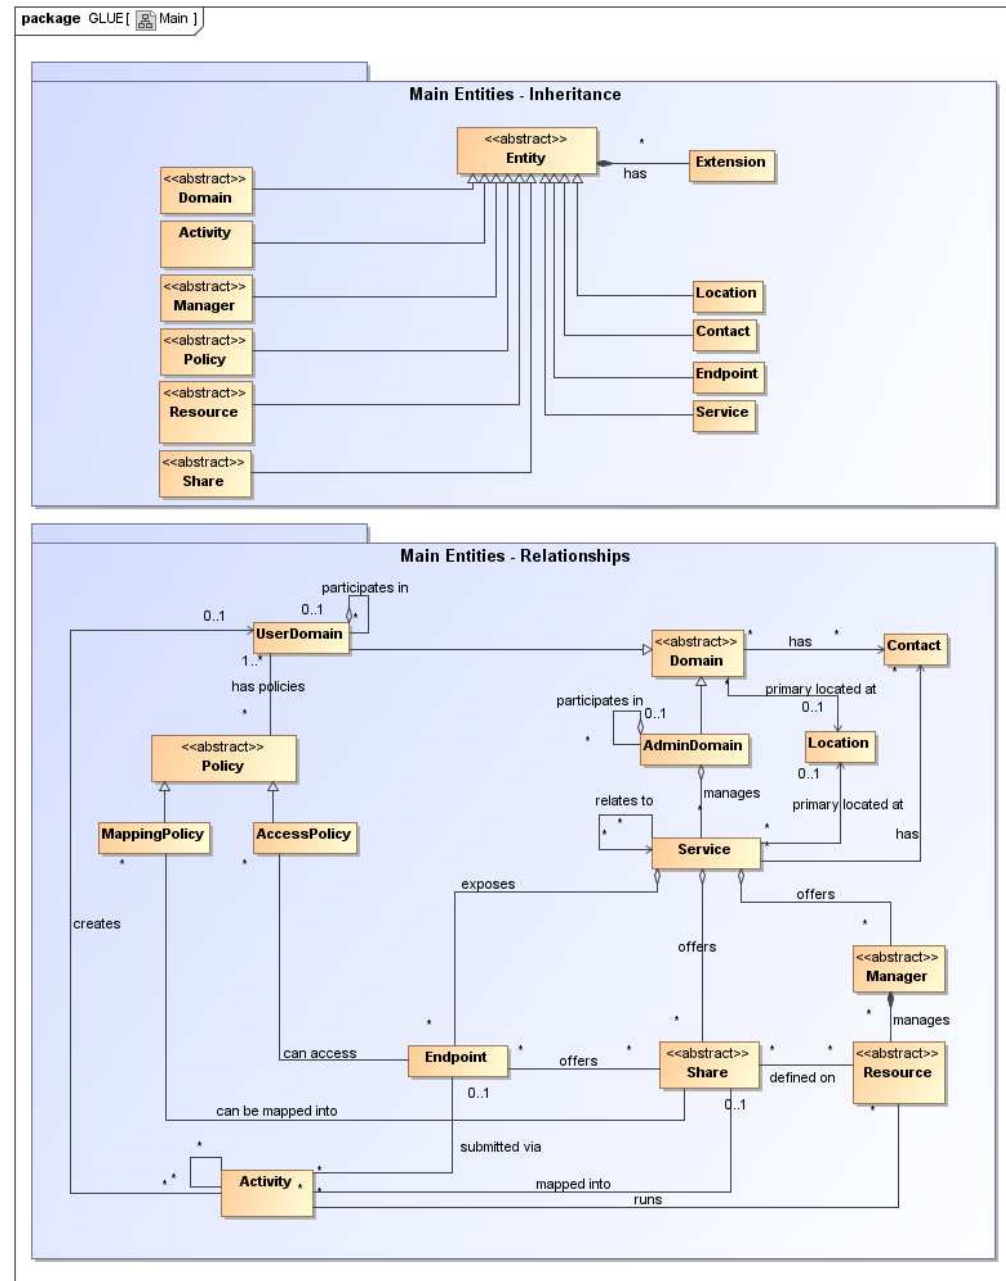

Figure 1 Entities and relationships for the Main Entities conceptual model

Formatted: Heading 2

## 5.1 Entity

| Entity                 | Inherits from |       |  | Description   |
|------------------------|---------------|-------|--|---|
| Entity<br><<abstract>> |               |       |  | Abstract root concept from which all the other concepts are derived (except the Extension class); it has metadata about information creation and validity plus a key-value pair extension mechanism |
| Attribute              | Type          | Mult. | Unit   | Description   |
| CreationTime           | DateTime_t    | 0..1  |  | Timestamp describing when the entity instance was generated   |
| Validity               | UInt64        | 0..1  | s  | The duration after CreationTime that the information presented in the Entity MAY be considered relevant. After that period has elapsed, the information SHOULD NOT be considered relevant           |
| ID [key]               | URI           | 1     |  | A global unique ID  |
| Name                   | String        | 0..1  |  | Human-readable name   |
| OtherInfo              | String        | *     |  | Placeholder to publish info that does not fit in any other attribute. Free-form string, comma-separated tags, (name, value ) pair are all examples of valid syntax                                  |
| Association End        |               | Mult. | Description  |   |
| Extension.Key          |               | *     | The entity MAY be associated to zero or more key-value pairs |   |

Deleted: Property

Deleted: can

This entity is the root entity from which all the GLUE classes inherit (exception is made for the Extension class). The specialized classes will inherit both the association to the Extension class and both the properties CreationTime and Validity. While the inheritance to the Extension class is reported in each table, the inheritance of the two properties is not explicitly listed.

## 5.2 Extension

| Entity          | Inherits from |       |   | Description   |
|-----------------|---------------|-------|---|---|
| Extension       |               |       |   | A key,value pair enabling the association of extra information not captured by the model with an Entity instance  |
| Attribute       | Type          | Mult. | Unit  | Description   |
| Key             | String        | 1     |   | An identifier local to the container class instance; typically an attribute name not present in the model; this identifier is not supposed to be unique; several instances of this class MAY hold the same value for this attribute |
| Value           | String        | 1     |   | A value for the attribute   |
| Association End |               | Mult. | Description   |   |
| Entity          |               | 1     | The key, value pair is associated to an entity instance |   |

Deleted: can

The location entity **MAY** be used for describing geographical positions of domains and services. The aim is to provide a simple way to express geographical information and it is not intended to be used in complex geographical information systems. The accuracy of latitude and longitude should be defined in a future interoperability profile defined by projects adopting this specification.

This entity MAY be used to represent contact information for requests related to different areas (e.g., user support, security or sysadmin). The various types of contact are identified by the Type attribute. In case of time-depend contact information, the instances of this entity should represent only the active contact information.

**Deleted:** can

There are several specifications recommending how to embed contacts into URI. The following specifications SHOULD be used:

- telephone and fax: <http://www.ietf.org/rfc/rfc2806.txt>
- email: <http://www.ietf.org/rfc/rfc2368.txt>
- irc: <http://www.w3.org/Addressing/draft-mirashi-uri-irc-01.txt>

## 5.5 Domain

| Entity                 | Inherits from                |             |          | Description  |

In the GLUE Information Model, the UserDomain class **SHOULD** be used to capture the concept of Virtual Organization (VO). By VO, we mean a set of individuals and/or institutions having direct access to computers, software, data, and other resources for collaborative problem-solving or other purposes. Resources utilized by a VO are expected to be accessible via network endpoints and constrained by defining utilization targets called shares. The VO **MAY** exhibit the internal structure in terms of groups of individuals, each of them being a UserDomain. UserDomains **MAY** be hierarchically structured. The "participates in" association **MAY** represent this structure.

As regards the UserManager, it is **RECOMMENDED** that its value is an Endpoint ID enabling to discover the related class instance and inherent attributes. An example of User Manager is the VOMS (Virtual Organization Membership Service, <http://voms.forge.cnaf.infn.it/>).

**Deleted:** In the GLUE Information Model, the Virtual Organization can be realized by using the concept of UserDomain. If the VO has an internal structure, this can be represented by using different domains related to each other. A Virtual Organization (VO) comprises a set of individuals and/or institutions having direct access to computers, software, data, and other resources for collaborative problem-solving or other purposes. Resources utilized by a VO are expected to be accessible via network endpoints and constrained by defining utilization targets called shares. The VO can exhibit the internal structure in terms of groups of individuals, each of them being a UserDomain. UserDomains can be hierarchically structured. This structure can be represented via the "participates in" association.¶

## 5.6 Service

| Entity              | Inherits from     | Description  |      |  |
|---------------------|-------------------|--|------|--|
| Service             | Entity            | An abstracted, logical view of actual software components that participate in the creation of an entity providing one or more functionalities useful in a Grid environment. A service exposes zero or more endpoints having well-defined interfaces, zero or more shares and zero or more managers and the related resources. The service is autonomous and denotes a weak aggregation among endpoints, the underlying managers and the related resources, and the defined shares. The service enables to identify the whole set of entities providing the functionality with a persistent name. |      |  |
| Inherited Attribute | Type              | Mult.  | Unit | Description  |
| <u>CreationTime</u> | <u>DateTime_t</u> | <u>0..1</u>  |      | <u>Timestamp describing when the entity instance was generated</u>   |
| <u>Validity</u>     | <u>UInt64</u>     | <u>0..1</u>  | s    | <u>The duration after CreationTime that the information presented in the Entity MAY be considered relevant. After that period has elapsed, the information SHOULD NOT be considered relevant</u> |
| <u>ID</u> [key]     | <u>URI</u>        | <u>1</u>   |      | <u>A global unique ID</u>  |
| <u>Name</u>         | <u>String</u>     | <u>0..1</u>  |      | <u>Human-readable name</u>   |
| <u>OtherInfo</u>    | <u>String</u>     | <u>*</u>   |      | <u>Placeholder to publish info that does not fit in any other attribute. Free-form string, comma-separated tags, (name, value) pair are all examples of valid syntax</u>                         |
| Attribute           | Type              | Mult.  | Unit | Description  |
| Capability          | Capability_t      | *  |      | The provided capability according to the Open Grid Service Architecture (OGSA) architecture [OGF-GFD80] (it is given by the sum of all the capabilities provided by the related endpoints)       |

|                           |                |       |   |   |                            |
|---------------------------|----------------|-------|---|---|----------------------------|
| Type                      | ServiceType_t  | 1     |   | The type of service according to a <u>namespace-based</u> classification ( <u>the namespace MAY be related to a middleware name, an organization or other concepts; org.glue and org.ogf are reserved</u> ) | Deleted: middleware        |
| QualityLevel              | QualityLevel_t | 1     |   | Maturity of the service in terms of quality of the software components; <u>the value corresponds to the highest quality level among the available endpoints</u>   |                            |
| StatusInfo                | URI            | *     |   | Web page providing additional information like monitoring aspects   | Deleted: Page              |
| Complexity                | String         | 0..1  |   | Human-readable summary description of the complexity in terms of the number of endpoint types, shares and resources. The syntax should be: endpointType=X, share=Y, resource=Z.                             | Deleted: OtherInfo ... [8] |
| Association End           |                | Mult. | Description   |   |                            |
| Endpoint.ID               |                | *     | A service exposes zero or more endpoints              |   |                            |
| Share.LocalID             |                | *     | A service offers zero or more shares                  |   |                            |
| Manager.ID                |                | *     | A service offers zero or more managers                |   |                            |
| Contact.ID                |                | *     | A service has zero or more contacts                   |   |                            |
| Location.ID               |                | 0..1  | A service is primary located at a location            |   |                            |
| Service.ID                |                | *     | A service is related to zero or more services         |   |                            |
| Service.ID                |                | *     | A service is related to zero or more services         |   |                            |
| Inherited Association End |                | Mult. | Description   |   |                            |
| Extension.Key             |                | *     | The entity <u>MAY</u> be extended via key-value pairs |   |                            |

The simplest Service aggregates an endpoint, no share, no manager and no resource (e.g., a metadata catalog service). In the context of a Service, the same resource MAY be exposed via multiple endpoints based on the defined shares. For instance, in the area of storage systems, two endpoints implementing SRMv1 [srmv1] and SRMv2.2 [srmv2] interfaces respectively MAY expose the same resource via different endpoints offering different interface version; in the area of computing systems, the CREAM [cream] and GRAM [gram] endpoints MAY expose the resources locally managed by the same manager (typically a batch system). Endpoints, Shares, Managers and Resources MUST belong to precisely one service.

## 5.7 Endpoint

| Entity              | Inherits from        | Description   |          |  | Formatted: Bullets and Numbering |
|---------------------|----------------------|---|----------|--|----------------------------------|
| Endpoint            | Entity               | A network location having a well-defined interface and exposing the service functionalities |          |  |                                  |
| Inherited Attribute | Type                 | Mult.   | Unit     | Description  | Formatted Table                  |
| <u>CreationTime</u> | <u>DateTime_t</u>    | <u>0..1</u>   |          | <u>Timestamp describing when the entity instance was generated</u>   |                                  |
| <u>Validity</u>     | <u>UInt64</u>        | <u>0..1</u>   | <u>s</u> | <u>The duration after CreationTime that the information presented in the Entity MAY be considered relevant. After that period has elapsed, the information SHOULD NOT be considered relevant</u> |                                  |
| <u>ID</u> [key]     | <u>URI</u>           | <u>1</u>  |          | <u>A global unique ID</u>  |                                  |
| <u>Name</u>         | <u>String</u>        | <u>0..1</u>   |          | <u>Human-readable name</u>   |                                  |
| <u>OtherInfo</u>    | <u>String</u>        | <u>*</u>  |          | <u>Placeholder to publish info that does not fit in any other attribute. Free-form string, comma-separated tags, (name, value) pair are all examples of valid syntax</u>                         |                                  |
| Attribute           | Type                 | Mult.   | Unit     |  | Deleted: Property                |
| URL                 | URI                  | 1   |          | Network location of the endpoint to contact the related service  | Deleted: ID [key] ... [9]        |
| Capability          | Capability_t         | *   |          | The provided capability according to the OGSa architecture   | Deleted: 1..                     |
| Technology          | EndpointTechnology_t | 0..1  |          | Technology used to implement the   |                                  |

|                           |                       |       |   |
|---------------------------|-----------------------|-------|---|
|                           |                       |       | endpoint  |
| InterfaceName             | URI                   | 1     | Identification of a of the interface  |
| InterfaceVersion          | String                | 0..*  | Version of the interface  |
| InterfaceExtension        | URI                   | *     | Identification of an extension to the interface   |
| WSDL                      | URI                   | *     | URL of the WSDL document describing the offered interface (applies to Web Services endpoint)  |
| SupportedProfile          | URI                   | *     | URI identifying a supported profile   |
| Semantics                 | URI                   | *     | URI of a document providing a human-readable description of the semantics of the endpoint functionalities                                       |
| Implementor               | String                | 0..1  | Main organization implementing this software component  |
| ImplementationName        | String                | 0..1  | Name of the implementation  |
| ImplementationVersion     | String                | 0..1  | Version of the implementation (the syntax MAY be: major.minor.patch)  |
| QualityLevel              | QualityLevel_t        | 1     | Maturity of the endpoint in terms of quality of the software components   |
| HealthState               | EndpointHealthState_t | 1     | A state representing the health of the endpoint in terms of its capability of properly delivering the functionalities                           |
| HealthStateInfo           | String                | 0..1  | Textual explanation of the state endpoint   |
| ServingState              | ServingState_t        | 1     | A state specifying if the endpoint is accepting new requests and if it is serving the already accepted requests                                 |
| StartTime                 | DateTime_t            | 0..1  | The timestamp for the start time of the endpoint  |
| IssuerCA                  | DN_t                  | 0..1  | Distinguished name of Certification Authority issuing the certificate for the endpoint  |
| TrustedCA                 | DN_t                  | *     | Distinguished name of the trusted Certification Authority (CA), i.e., certificates issued by the CA are accepted for the authentication process |
| DowntimeAnnounce          | DateTime_t            | 0..1  | The timestamp for the announcement of the next scheduled downtime   |
| DowntimeStart             | DateTime_t            | 0..1  | The timestamp describing when the next downtime is scheduled to start   |
| DowntimeEnd               | DateTime_t            | 0..1  | The timestamp describing when the next downtime is scheduled to end   |
| DowntimeInfo              | String                | 0..1  | Description of the next scheduled downtime  |
| Association End           |                       | Mult. | Description   |
| Service.ID                |                       | 1     | An endpoint is part of a Service  |
| Share.LocalID             | <<abstract>>          | *     | An endpoint MAY pass activities to zero or more Shares  |
| AccessPolicy.ID           |                       | *     | An endpoint has associated zero or more AccessPolicies  |

For Grid services requiring a richer set of properties for the endpoint, specific models MAY be derived by specializing from the Endpoint entity and adding new properties or relationships. The current proposal contains the ComputingEndpoint specialization (see Section 6.2) and the StorageEndpoint specialization (see Section 7.4).

The endpoint network location MUST be encoded as a URI. When available, standard schemes for the encoding SHOULD be used (e.g., for Java Messaging Service <http://www.ietf.org/internet-drafts/draft-merrick-jms-uri-03.txt>).

Concerning the SupportedProfile attribute, if there is no recommended URI for the identification of a certain profile, then suggestions for choosing them are: main URL of the document specifying

Deleted: property

the profile or target namespace URI (in case of XML Schema representation of the profile).

### 5.8 Share

| Entity                    | Inherits from            |             |          | Description  |
|---------------------------|--------------------------|-------------|----------|--|
| Share<br><<abstract>>     | Entity                   |             |          | A utilization target for a set of resources managed by a local manager and offered via related endpoints. The share is defined by configuration parameters and characterized by status information |
| Inherited Attribute       | Type                     | Mult.       | Unit     | Description  |
| <u>CreationTime</u>       | <u>DateTime</u> <i>t</i> | <u>0..1</u> |          | <i>Timestamp describing when the entity instance was generated</i>   |
| <u>Validity</u>           | <u>UInt64</u>            | <u>0..1</u> | <u>s</u> | <i>The duration after CreationTime that the information presented in the Entity MAY be considered relevant. After that period has elapsed, the information SHOULD NOT be considered relevant</i>   |
| <u>ID</u> [key]           | <u>URI</u>               | <u>1</u>    |          | <i>A global unique ID</i>  |
| <u>Name</u>               | <u>String</u>            | <u>0..1</u> |          | <i>Human-readable name</i>   |
| <u>OtherInfo</u>          | <u>String</u>            | <u>-</u>    |          | <i>Placeholder to publish info that does not fit in any other attribute. Free-form string, comma-separated tags, (name, value) pair are all examples of valid syntax</i>                           |
| Attribute                 | Type                     | Mult.       | Unit     | Description  |
| Description               | String                   | 0..1        |          | Description of this share  |
| Association End           | Mult.                    |             |          | Description  |
| Endpoint.ID               | *                        |             |          | A share is consumed via one or more endpoints  |
| Resource.ID               | <<abstract>>             |             |          | A share is defined on one or more resources  |
| Service.ID                | 1                        |             |          | A share participates in a service  |

This is an abstract entity not meant to be instantiated. It SHOULD be used in order to derive specialized entities.

The manager refers typically to a local manager service which specific details are abstracted by a middleware software component (endpoint). Examples of managers are: for computing resources, batch systems such as OpenPBS or LSF; for storage resources, GPFS.

### 5.10 Resource

| Entity  | Inherits from     |       |      | Description   |
|---|-------------------|-------|------|---|
| Resource<br><<abstract>>  | Entity            |       |      | An entity providing a capability or capacity, managed by a local software component (manager), part of a logical service, reachable via one or more endpoints and having one or more shares defined on it. A resource <b>MAY</b> refer to a category with summary information on the available instances. |
| Inherited Attribute   | Type              | Mult. | Unit | Description   |
| <u>CreationTime</u>   | <u>DateTime</u> t | 0..1  |      | <u>Timestamp describing when the entity instance was generated</u>  |
| <u>Validity</u>   | <u>UInt64</u>     | 0..1  | s    | <u>The duration after CreationTime that the information presented in the Entity MAY be considered relevant. After that period has elapsed, the information SHOULD NOT be considered relevant</u>  |
| <u>ID</u> [key]   | <u>URI</u>        | 1     |      | <u>A global unique ID</u>   |
| <u>Name</u>   | <u>String</u>     | 0..1  |      | <u>Human-readable name</u>  |
| <u>OtherInfo</u>  | <u>String</u>     | *     |      | <u>Placeholder to publish info that does not fit in any other attribute. Free-form string, comma-separated tags. (name, value ) pair are all examples of valid syntax</u>   |
| Attribute   | Type              | Mult. | Unit | Description   |
| <u>No extra properties are defined in the specialized entity.</u> |                   |       |      |   |
| Association End   |                   | Mult. |      | Description   |
| Manager.ID  | <<abstract>>      | 1     |      | A resource is managed by a manager  |
| Share.LocalID   | <<abstract>>      | *     |      | A resource provides capacity in terms of shares   |
| Activity.ID   |                   | *     |      | A resource runs zero or more activities   |
| Inherited Association End   |                   | Mult. |      | Description   |
| Extension.Key   |                   | *     |      | The entity <b>MAY</b> be extended via key-value pairs   |

Deleted: can

Grid jobs (named Computing Activities in GLUE) are example of activities for a Computing Service. An interesting type of relationship for jobs derives from its propagation through several services. For instance, a broker service submits a Grid job to a selected execution service, upon completion the execution service submits a logging record to an accounting service. Each of these services will have associated an instance of a Grid job related to the lifecycle of the job within the service. All instances refer to the same conceptual job submitted by the user.

### 5.12 Policy

| Entity                    | Inherits from     |             |  | Description  |
|---------------------------|-------------------|-------------|--|--|
| Policy<br><<abstract>>    | Entity            |             |  | Statements, rules or assertions that specify the correct or expected behavior of an entity   |
| Inherited Attribute       | Type              | Mult.       | Unit   | Description  |
| <u>CreationTime</u>       | <u>DateTime_t</u> | <u>0..1</u> |  | <u>Timestamp describing when the entity instance was generated</u>   |
| <u>Validity</u>           | <u>UInt64</u>     | <u>0..1</u> | <u>s</u>                                       | <u>The duration after CreationTime that the information presented in the Entity MAY be considered relevant. After that period has elapsed, the information SHOULD NOT be considered relevant</u> |
| <u>ID</u> [key]           | <u>URI</u>        | <u>1</u>    |  | <u>A global unique ID</u>  |

Deleted: LocalID ... [13]

Deleted: can

This is an abstract entity not meant to be instantiated.

In this document, we provide the definition for a "basic" scheme (see Appendix 17.4). Such a scheme is designed to be simple and is inspired by real world scenarios in current production Grid systems. The Rule **attribute** implicitly contains the reference to the User Domains, therefore, in the concrete data model mapping, we RECOMMEND to not representing the association between User Domain and Access Policy or Mapping Policy explicitly since it is already captured by the Rule.

Deleted: 17.3

Deleted: property

For a given entity to which policies are associated (i.e., Endpoint and AccessPolicy, Share and MappingPolicy), several instances of the Policy class **MAY** be defined. This is allowed in order to enable to advertise policies using different schemes. We RECOMMEND that only one instance per policy scheme is associated to the same entity instance. The evaluation algorithm for the rules SHOULD be defined by the policy scheme.

Deleted: can

If an entity instance is associated to different Policy instances, each of them based on a different scheme, then the evaluation process SHOULD consider each set of policies independently. This means that the evaluation SHOULD rely on a certain policy scheme which is selected and understood by the consumer, and not by composing policies expressed using different schemes.

#### 5.12.1 AccessPolicy

| Entity  | Inherits from         | Description   |  |  |
|---|-----------------------|---|--|--|
| AccessPolicy  | Policy                | Statements, rules or assertions that provide coarse-granularity information about the access by actors to an endpoint |  |  |
| Inherited Attribute                                       | Type                  | Mult  | Unit   | Description  |
| <u>CreationTime</u>                                       | <u>DateTime_t</u>     | <u>0..1</u>   |  | <u>Timestamp describing when the entity instance was generated</u>   |
| <u>Validity</u>   | <u>UInt64</u>         | <u>0..1</u>   | <u>s</u>                                       | <u>The duration after CreationTime that the information presented in the Entity MAY be considered relevant. After that period has elapsed, the information SHOULD NOT be considered relevant</u> |
| <u>ID</u> [key]   | <u>URI</u>            | <u>1</u>  |  | <u>A global unique ID</u>  |
| <u>Name</u>   | <u>String</u>         | <u>0..1</u>   |  | <u>Human-readable name</u>   |
| <u>OtherInfo</u>  | <u>String</u>         | <u>*</u>  |  | <u>Placeholder to publish info that does not fit in any other attribute. Free-form string, comma-separated tags. (name, value) pair are all examples of valid syntax</u>                         |

## 6 Conceptual Model of the Computing Service

The conceptual model of the Computing Service is based upon the main entities and uses specializations of Service, Endpoint, Share, Manager, Resource, and Activity entities. Further computing related concepts such as Application Environment, Application Handle and Benchmark are introduced.

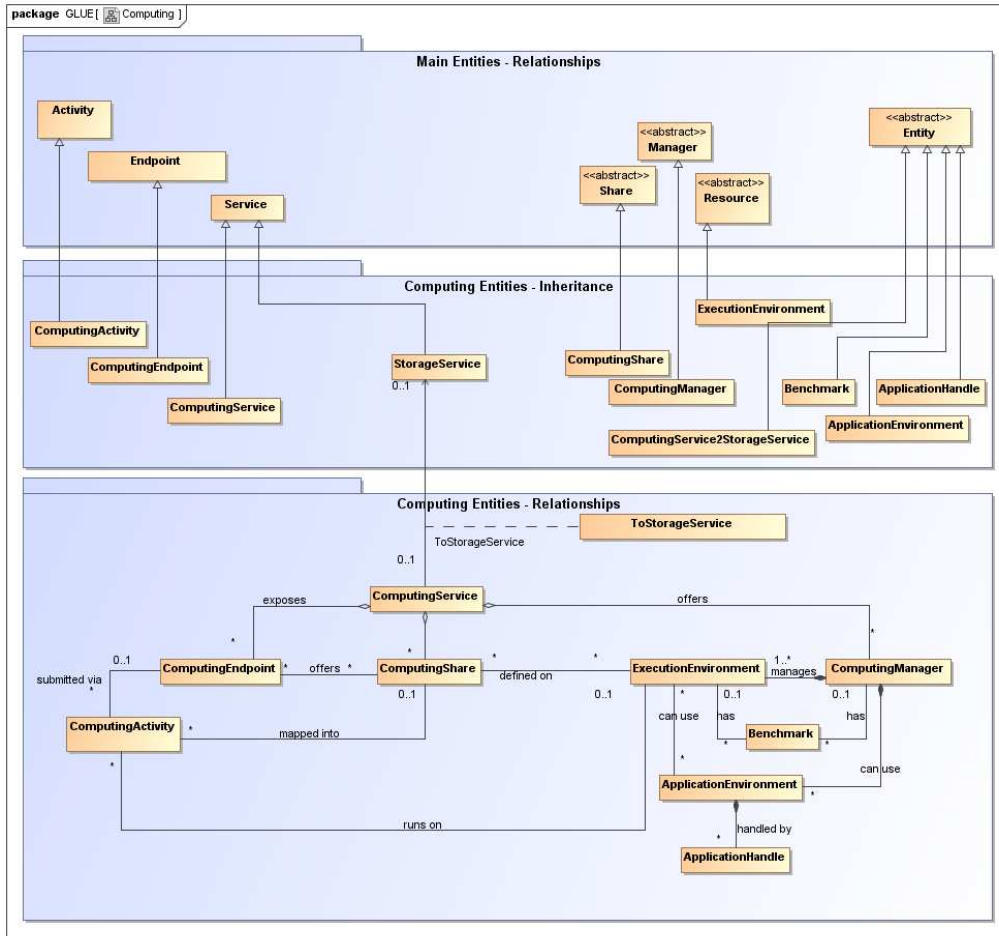

Figure 2 Entities and relationships for the Computing Service conceptual model

In this section, we extensively use the concept of physical CPU, logical CPU and slot:

- a physical CPU is defined by the socket, that means there is one physical CPU per socket; (e.g., a multi-core CPU counts as one physical CPU)
- a logical CPU corresponds to a CPU as visible by the operating system running either on a real or virtual machine
- a slot is a portion of executable time in a logical CPU offered by an execution environment instance which **MAY** be consumed by a job
  - usually, there is one slot per logical CPU, nevertheless a logical CPU **MAY** be shared across different slots

Deleted: can

Deleted: can

- jobs MAY consume several slots at the same time (e.g., MPI jobs); a multi-slot job is counted as one job

Deleted: can

Throughout the specification, we also use the concept of storage extent to mean the capabilities and management of the various media that exist to store data and allow data retrieval.

## 6.1 ComputingService

Formatted: Normal, Justified

The ComputingService class is a specialization of the Service class for a service offering computational capacity. The ComputingService entity is the main logical unit, and aggregation point for several entities altogether modeling a computing capability in a Grid system. A ComputingService is capable executing ComputingActivities on its associated resources. The resources behind the ComputingService are described via the ComputingManager, ExecutionEnvironment, ApplicationEnvironment, ApplicationHandle and Benchmark entities. The governing policies and status of the resources are given by the ComputingShare elements. The ComputingActivities of a ComputingService are submitted and controlled via ComputingEndpoint.

|                     |                |  |      |   |
|---------------------|----------------|--|------|---|
| Entity              | Inherits from  | Description  |      |   |
| ComputingService    | Service        | <p>An abstracted, logical view of actual software components that participate in the creation of a computational capacity in a Grid environment. A computing service exposes zero or more computing endpoints having well-defined interfaces, zero or more computing shares and zero or more computing managers and the related execution environments.</p> <p>The computing service is autonomous and denotes a weak aggregation among computing endpoints, the underlying computing managers and related execution environments, and the defined computing shares. The computing service enables to identify the whole set of entities providing the computing functionality with a persistent name.</p> |      |   |
| Inherited Attribute | Type           | Mult   | Unit | Description   |
| CreationTime        | DateTime_t     | 0..1   |      | Timestamp describing when the entity instance was generated   |
| Validity            | UInt64         | 0..1   | s    | The duration after CreationTime that the information presented in the Entity MAY be considered relevant. After that period has elapsed, the information SHOULD NOT be considered relevant   |

The simplest computing service is formed by a computing endpoint exposing an interface for job submission and control.

In case of a single computing manager whose execution environments are exposed by multiple computing endpoints, both computing manager, execution environments and computing endpoints MUST be considered as part of the same computing service. In case of a single computing endpoint exposing execution environments managed by different computing managers, then the computing endpoint, the execution environments and the related computing managers MUST be considered as part of the **same** computing service.

The computing service always aggregates computing endpoints, computing shares, computing managers and execution environments forming a connected set. In other words, Endpoint A exposing Execution Environment A of Manager A via Share A and Endpoint B exposing Execution Environment B of Manager B via Share B form two different computing services. On the other side, Endpoint A exposing Execution Environment A of Manager A via Share A and Endpoint B exposing Execution Environment A of Manager A via Share B form one Computing Service.

## 6.2 ComputingEndpoint

ComputingEndpoint is a specialization of the Endpoint class for a service possessing computational capability. The class represents an endpoint which is used to create, control and monitor computational activities. The computational specific information contains service load related parameters, staging capability and supported jobdescription. This class provides attributes that MAY be used to publish summary information of jobs submitted via a certain endpoint. Such attributes are optional and are not always measurable (e.g., in case of a stateless endpoint).

### 6.3 ComputingShare

The computing share is the specialization of the main share entity for computational services. A computing share is a high-level concept introduced to model the utilization target for a set of execution environments defined by a set of configuration parameters and characterized by status information. A ComputingShare carries information about "policies" (limits) defined over a set of subset of resources and describes their dynamic status (load).

In clusters managed by a batch system, the simplest way to set up a computing share is to configure a batch queue, nevertheless, the same computing share MAY be implemented using different batch system configuration strategies. In complex batch systems, a batch queue MAY be configured with different set of policies for different set of users. This implies that each set of users obtains a different utilization target. Such a scenario MAY be represented by different computing shares. In general, given a number of shares to be set up, it is possible to adopt different configuration strategies in the underlying system. Regardless the selected approach, the external behavior does not change. The main goal of the computing share concept is to abstract from such implementation choices and to represent the externally observable behavior.

The introduction of the computing share concept supports also the modelling of heterogeneity within a ComputingService by being able to have associations to different execution environments.

Deleted: can

As regards CPU Time and Wall Time related properties, there is the need for a way to normalize them depending on the computing capacity of the execution environment. The approach proposed in GLUE is to add two attributes in the Execution Environment (see Section 6.6) which refer to the scaling factor to be used to compute the CPU/Wall time that a job will get if it will be assigned to such an execution environment via a certain share. It is important that a job will get always at least the advertised CPU/Wall time. This means that the reference Execution Environment for the normalization should be always the fastest among those available in the whole Computing Service. For this Execution Environment, the scaling factor **MUST** be equal to 1. The CPU/Wall time values published by a share refer to the time that the job will get when mapped to this Execution Environment. For the other Execution Environments, the time should be normalized according to the defined scaling factors.

Deleted: 6.6

#### 6.4 ComputingManager

ComputingManager is a specialization of the Manager class for the computational capability. The ComputingManager is responsible for the local control of resources and this layer is not exposed directly to external clients. The operating system MAY be the simplest case of a computing manager though the ComputingManager is often realized by means of a Local Resource Management (LRMS) "batch" system. The class provides aggregated information on controlled resources and also describes local storage extents needed for Grid enabled ComputingService.

| Entity           | Inherits from | Description   |
|------------------|---------------|---|
| ComputingManager | Manager       | A software component locally managing one or more execution environments. It <u>MAY</u> describe also aggregated information about the managed resources. The computing manager is also known as Local Resource Management System (LRMS). |

| Inherited Attribute   | Type                   | Mult        | Unit     | Description  |
|-----------------------|------------------------|-------------|----------|--|
| <u>CreationTime</u>   | <u>DateTime</u>        | <u>0..1</u> |          | <u>Timestamp describing when the entity instance was generated</u>   |

| Association End                                 |        | Mult. | Description  |   |
| ComputingService.ID [redefines Service.ID]      |        | 1     | A computing manager participates in a computing service                  |   |
| ExecutionEnvironment.ID [redefines Resource.ID] |        | *     | A computing manager manages one or more execution environments           |   |
| ApplicationEnvironment.LocalID                  |        | *     | A computing manager <b>MAY</b> use zero or more application environments |   |
| Benchmark.LocalID                               |        | *     | A computing manager has zero or more associated benchmarks               |   |
| Inherited Association End                       |        | Mult. | Description  |   |
| Extension.Key                                   |        | *     | The entity <b>MAY</b> be extended via key-value pairs                    |   |

As regards the WorkingArea-related attributes and single-slot jobs, four scenarios should be considered. Both scenarios and related attribute values are presented in Table 1.

**Table 1 Working Area and Single-slot jobs scenarios**

| Working Area   | Shared | Guaranteed |
|--|--------|------------|
| one working area shared across all the execution environments and shared across simultaneous jobs  | true   | false      |
| one working area shared across all the execution environments with guaranteed quota to each job  | true   | true       |
| a working area local to each execution environment, but shared across all the jobs which run simultaneously in the given execution environment | false  | false      |
| a working area local to each execution environment and dedicated to each job   | false  | true       |

In case there is a dedicated working area for multi-slot jobs, this **SHOULD** be represented by the **WorkingAreaMultiSlot\*** attributes. In case there is no dedicated working area for multi-slot jobs,

i.e., there is a common working area for both single-slot and multi-slot jobs, we RECOMMEND to publish only the attributes related to the working area for single-slot jobs.

The Operating System MAY be the simplest case of computing manager. A typical example of computing manager is a batch system (i.e., LRMS).

## 6.5 Benchmark

The Benchmark class characterizes the relative performance of the computing resource through providing the result of a specific benchmark suite executed on the computing resource behind the Computing Service. The Benchmark class provides the both the type and the value of the benchmark suite.

## 6.6 ExecutionEnvironment

The ExecutionEnvironment class describes the hardware and operating system environment in which a job will run. It represents a set of homogeneous Worker Nodes, so if a computing system contains nodes with significantly different properties there MAY be several ExecutionEnvironment instances. This implies that it should be possible to request a specific environment when a job is submitted. The ExecutionEnvironment MAY refer to virtual rather than physical machines.

Formatted: Justified

As well as attributes describing a typical node, the class gives summary information about the size and usage of the set of nodes which possess those properties. However, there is no way to relate these to the information in other entities, e.g. it is not possible to know which jobs in a given ComputingShare are running on which ExecutionEnvironment.

Formatted: Normal, Justified

| Entity               | Inherits from |       |      | Description   |
|----------------------|---------------|-------|------|---|
| ExecutionEnvironment | Resource      |       |      | A type of environment available to and requestable by a Grid job when submitted to a ComputingService via a Computing Endpoint; the type of environment is described in terms of hardware, operating system and network characteristics; the information about the total/available/used instances of this type of execution environment are also included |
| Inherited Attribute  | Type          | Mult. | Unit | Description   |
| CreationTime         | DateTime_t    | 0..1  |      | Timestamp describing when the entity instance   |

Deleted: can

Each execution environment instance is under the responsibility of a Computing Manager (i.e., LRMS). An execution environment MAY be realized in several ways. Examples are a computing node or a virtual machine image that MAY be requested by a job (different virtual machine images MAY coexist on the same node). The description about individual software packages is considered by the ApplicationEnvironment class.

## 6.7 ApplicationEnvironment

The ApplicationEnvironment class describes the software environment in which a job will run, i.e. what pre-installed software will be available to it. Each Application is identified by a name (the AppName attribute); these names are not defined within the schema, but SHOULD be assigned in a way which allows applications to be uniquely identified. The properties of installed software MAY vary substantially, but the attributes of the class cover the most common cases, in particular for licensed software. If necessary, additional information MAY be added using the OtherInfo attribute and the Extension class.

There is no recommendation for the Name attribute of the Application Environment. In some deployment scenario, the definition of namespace-based Names or guidelines for unique application names MAY be defined; application repository services relying on the unique application names MAY be provided. This aspect is considered out of scope for GLUE.

Deleted: property

Deleted: can

Deleted: can

The Application Environment is suggested to be used also for describing application software or special environment setup in terms of a simple tag. In this case, the Name attribute should be used.

Deleted: property

## 6.8 ApplicationHandle

The ApplicationHandle class is an extension to ApplicationEnvironment for applications which need to be set up in some way before they MAY be used. For each supported setup method a string MAY be specified, the interpretation of which is specific to the method - in the simplest case this could just be a setup script to execute.

## 6.9 ComputingActivity

The ComputingActivity class represents a single (but possibly multi-processor) job. The attributes give the job properties and state as seen by the local batch system, together with some Grid-level information.

| Activity.ID   | *     | An activity is related to zero or more activities            |
| Activity.ID   | *     | An activity is related to zero or more activities            |

Deleted: can

In this specification, the Computing Activity refers to simple jobs or element of collections or workflow. The description of the relationships between jobs part of a collection or workflow **MAY** be considered in future revisions of the specification.

Deleted: may

As regards the State **attribute** and the related ComputingActivityState\_t type, we notice that currently there is no commonly accepted state model. Each production Grid middleware defined and is using its own state model. As regards the standardization process, the OGSA-BES specification defines a simple state model. The middleware providers started to define their own extensions to the BES state model, nevertheless they differ and do not enable interoperability. Given the current scenario, we RECOMMEND to use namespace in state model values, so that every middleware provider **MAY** publish the computing activity state according to its definition. We expect that an extension to the core BES state model common to all the middleware providers and suitable for production scenarios **MAY** be defined by a profiling activity of the BES/JSDL/GLUE specifications.

#### 6.10 ToStorageService

The ToStorageService class represents the case where a filesystem from a Storage Service is available to jobs running on a Computing Service via POSIX access, e.g. as an NFS mount. Each ToStorageService instance represents a single mount point. It is assumed that such mounts are available on all nodes (i.e. all Execution Environments) in the Computing Service.

## 7 Conceptual Model of the Storage Service

The conceptual model of the Storage Service is based upon the main entities and uses specializations of Service, Endpoint, Share, Manager, Resource, and Activity entities. Further storage related concepts such as Storage Service Capacity, Storage Share Capacity and Storage Access Protocol are introduced.

Figure 3 Entities and relationships for the Storage Service conceptual model

As explained in Section 6, we use the concept of storage extent to mean the capabilities and management of the various media that exist to store data and allow data retrieval.

Formatted: Normal, Left

## 7.1 StorageService

A StorageService represents a Grid-enabled storage system, most often hosted by a single site, but possibly distributed over multiple sites. A StorageService makes StorageShares of given properties available to selected UserDomains, typically (not necessarily) through one or more explicitly identified StorageEndpoints. Data MAY be stored in or retrieved from StorageShares through one or more StorageAccessProtocols. A StorageShare is a composition of chunks from one or more DataStores. StorageShares MAY overlap. A DataStore represents a physical device that MAY hold data (e.g. a disk or a tape robot). Each DataStore is managed by a StorageManager, an instance of a particular product identified by the ProductName and ProductVersion. StorageServiceCapacity objects summarize capacity-related information for which details MAY be available associated to StorageShares and DataStores.

Deleted: Local

Deleted: can

The storage service **MAY** expose storage endpoints enabling to manage or access different types of storage capacity. The usage of storage capacity is typically constrained by policies, thus implying service differentiation. Each homogenously constrained storage capacity is described by the storage share concept.

Deleted: can

The storage capacity used to create shares is locally managed by a storage manager and provided by data stores.

Deleted: storage resource

## 7.2 StorageServiceCapacity

A StorageServiceCapacity summarizes capacity-related information for all the StorageShares and DataStores of a given homogeneous type. The summaries **MAY** be compared to the sums of the relevant StorageShareCapacity attributes for the StorageShares of the given type. Capacities of overlapping StorageShares **MUST** only be counted once. An inconsistency between a summary value and the corresponding sum of relevant attributes **MAY** occur if part of the capacity is not explicitly published, or if the attributes concerned could not all be exactly determined or recorded at the same time. The summaries **MAY** also be compared to the sums of the relevant attributes of the DataStores of the given type, where inconsistencies **MAY** arise due to similar causes.

### 7.3 StorageAccessProtocol

A StorageAccessProtocol describes a protocol that MAY be used to store data in or retrieve data from StorageShares. The "file" protocol indicates that for ComputingServices given by ToComputingService objects the StorageShares are available through POSIX I/O. The mount point details are given by corresponding ToStorageService objects published by those ComputingServices. Most protocols require a negotiation between the client and a StorageEndpoint. For example, a StorageEndpoint implementing a version of the SRM protocol MAY be asked for a data transfer URL corresponding to a desired access protocol. An access protocol that does not require prior negotiation MAY be published as the Interface in a StorageEndpoint supporting that protocol [FIXME].

If a type of storage access protocol needs to be discoverable, then the storage access protocol class SHOULD be used. If a certain access protocol has a URL and this URL needs to be discoverable, then the access protocol SHOULD be also published via the storage endpoint.

### 7.4 StorageEndpoint

A StorageEndpoint represents a service that MAY be contacted by clients to manage StorageShares and to store or retrieve data. The StorageEndpoint typically implements a control protocol given by the Interface, which allows for the manipulation of StorageShares and the properties of their data content. Access to StorageShares for storing for retrieving data often has to be negotiated through the given control protocol. The available access protocols MAY be published in StorageAccessProtocol objects. The StorageEndpoint Interface MAY also indicate itself an access protocol that does not require prior negotiation [FIXME]. The StorageEndpoint

MAY be able to serve only a subset of the StorageShares within the StorageService, in which case that subset MAY be indicated through explicit associations with those StorageShares.

## 7.5 StorageShare

A StorageShare is a composition of chunks from one or more DataStores. StorageShares that overlap have the same SharingID, which in that case MUST neither be empty nor the string "dedicated". A DataStore represents a physical device that MAY hold data (e.g. a disk or a tape robot). A StorageShare need not be composed of homogeneous devices. The AccessLatency gives the maximum latency category for a file stored in the StorageShare to be made available for reading. For example, if the StorageShare comprises both disk and tape, and data MAY need to be recalled from tape, the published AccessLatency is "nearline". The RetentionPolicy indicates the probability of the StorageShare losing data. For example, "custodial" represents a very low probability, while "replica" indicates that the StorageShare is not suitable for keeping the only copy of precious data, but MAY be used for keeping a replica of such data. The ExpirationMode indicates what happens to data whose lifetime has expired, if ever. The Identifier allows the StorageShare to be given a tag that is meaningful for the UserDomain(s) served by the StorageShare. For example, for version 2.2 of the SRM control protocol a StorageShare would represent a Space and the Identifier the corresponding SpaceTokenUserDescription. Capacity-related information is made available through StorageShareCapacity objects. A StorageShare need not be available through StorageEndpoints not explicitly listed.

| ExpirationMode                                | ExpirationMode_t | 0..3  |   | Support for files with infinite and/or finite lifetimes, and what actions the storage service <b>MAY</b> take upon the expiration of a file | Deleted: may   |
| DefaultLifeTime                               | UInt32           | 0..1  | s   | The default lifetime assigned to the file if no explicit lifetime is specified  |  |
| MaximumLifeTime                               | UInt32           | 0..1  | s   | The maximum lifetime that <b>MAY</b> be requested for a file  | Deleted: can   |
| Tag   | String           | 0..1  |   | An <b>identifier defined by a user domain which identifies a share with a specific set of properties</b>                                    | Deleted: user defined tag for additional information |
| Association End                               |                  | Mult. | Description   |   |  |
| StorageEndpoint.ID<br>[redefines Endpoint.ID] |                  | *     | A storage share is consumed via zero or more endpoints        |   |  |
| DataStore.ID<br>[redefines Resource.ID]       |                  | *     | A storage share is defined on zero or more <b>data stores</b> |   |  |
| StorageService.ID<br>[redefines Service.ID]   |                  | 1     | A storage share participates in a storage service             |   |  |
| StorageShareCapacity.LocalID                  |                  | *     | A storage share offers zero or more storage share capacities  |   |  |
| Inherited Association End                     |                  | Mult. | Description   |   |  |
| Extension.Key                                 |                  | *     | The entity <b>MAY</b> be extended via key-value pairs         |   |  |
| MappingPolicy.ID                              |                  | *     | A share has zero or more mapping policies                     |   |  |

A storage share represents a utilization target of **one or more** storage **capacities** which policies are homogeneous. If many user domains are mapped to a storage share via a mapping policy, then they compete to the usage without any differentiation. A storage share **MAY** have many types of storage **capacities**. The status of each type of storage **capacity** as regards the usage by the user domains is described by the StorageShareCapacity.

## 7.6 StorageShareCapacity

The StorageShareCapacity class provides a set of attributes related to the size of the data storage associated with a StorageShare. One StorageShare MAY have several associated StorageShareCapacity objects of different Types, which MAY be related either to the physical nature of the storage medium or to the intended use, e.g. accounting or resource discovery. It is therefore possible that the same physical storage MAY be reported in more than one object. The size information relates to the values as seen by a user of the Service, which MAY not correspond directly to the size of the physical storage media which underly it.

The semantics of this class are the same as the StorageServiceCapacity class which represent the size of the entire Storage Service, but the classes are different since the relations are different. In general it cannot be assumed that the Storage Service Capacity is the sum of all the corresponding Storage Share Capacities, both because some information at the Share level MAY not be published, and because multiple StorageShare objects MAY share the same physical storage.

| Entity               | Inherits from | Description  |      |   |
|----------------------|---------------|--|------|---|
| StorageShareCapacity | Entity        | Description of the size and usage of an homogenous storage extent available to a storage share |      |   |
| Inherited Attribute  | Type          | Mult   | Unit | Description   |
| CreationTime         | DateTime_t    | 0..1   |      | Timestamp describing when the entity instance was generated   |
| Validity             | UInt64        | 0..1   | s    | The duration after CreationTime that the information presented in the Entity MAY be considered relevant. After that period has elapsed, the information SHOULD NOT be considered relevant |
| ID [key]             | URI           | 1  |      | A global unique ID  |
| Name                 | String        | 0..1   |      | Human-readable name   |
| OtherInfo            | String        | *  |      | Placeholder to publish info that does not fit in any other attribute. Free-form string, comma-  |

| Attribute                 | Type              | Mult. | Unit   | Description  |
|---------------------------|-------------------|-------|--|--|
| Type                      | StorageCapacity_t | 1     |  | Type of storage capacity   |
| TotalSize                 | UInt64            | 0..1  | GB   | Size of dedicated storage extent   |
| FreeSize                  | UInt64            | 0..1  | GB   | Size of free storage extent  |
| UsedSize                  | UInt64            | 0..1  | GB   | Size of used storage extent  |
| ReservedSize              | UInt64            | 0..1  | GB   | Size of reserved storage extent  |
| OtherInfo                 | String            | *     |  | Placeholder to publish info that does not fit in any other attribute. Free-form string, comma-separated tags, (name, value ) pair are all examples of valid syntax |
| Association End           |                   | Mult. | Description  |  |
| StorageShare.LocalID      |                   | 1     | A storage share capacity is related to one storage share |  |
| Inherited Association End |                   | Mult. | Description  |  |
| Extension.Key             |                   | *     | The entity <b>MAY</b> be extended via key-value pairs    |  |

The storage share capacity is useful to express the usage information of a homogenous storage extent allocated to a share. Such usage information refers to the user domains which are related to the storage share via mapping policies.

## 7.7 StorageManager

The StorageManager class represents the software system which manages the data storage media. If different media, e.g. tape and disk, are managed by different software systems there MAY be multiple StorageManager instances for a single StorageService. In some systems there MAY be a number of layers of software, but this cannot be represented. At present no attributes are defined beyond those inherited from the Manager entity, i.e. the Name and Version of the software product.

| Entity  | Inherits from | Description   |   |   |
|---|---------------|---|---|---|
| StorageManager  | Manager       | The primary software component locally managing one or more data stores. It MAY describe also aggregated information about the managed resources. |   |   |
| Inherited Attribute                                       | Type          | Mult.   | Unit  | Description   |
| CreationTime  | DateTime      | 0..1  |   | Timestamp describing when the entity instance was generated   |
| Validity  | UInt64        | 0..1  | s   | The duration after CreationTime that the information presented in the Entity MAY be considered relevant. After that period has elapsed, the information SHOULD NOT be considered relevant |
| ID [key]  | URI           | 1   |   | A global unique ID  |
| Name  | String        | 0..1  |   | Human-readable name   |
| OtherInfo   | String        | *   |   | Placeholder to publish info that does not fit in any other attribute. Free-form string, comma-separated tags, (name, value ) pair are all examples of valid syntax                        |
| ProductName   | String        | 1   |   | Name of the software product adopted as manager   |
| ProductVersion  | String        | 0..1  |   | Version of the software product adopted as manager  |
| Attribute   | Type          | Mult.   | Unit  | Description   |
| No extra properties are defined in the specialized entity |               |   |   |   |
| Association End   |               | Mult.   | Description   |   |
| StorageService.ID [redefines Service.ID]                  |               | 1   | A storage manager participates in a storage service   |   |
| DataStore.ID [redefines Resource.ID]                      |               | *   | A storage manager manages zero or more data stores    |   |
| Inherited Association End                                 |               | Mult.   | Description   |   |
| Extension.Key   |               | *   | The entity <b>MAY</b> be extended via key-value pairs |   |

7.8 DataStore

The DataStore class represents the physical storage systems underlying the Storage Service. Typically there will be one DataStore instance for each homogeneous type of storage, e.g. tape and disk. However, multiple objects of the same Type MAY be published if the storage is segmented at a high level, e.g. if there are two separate robotic tape stores.

| Entity   | Inherits from        | Description  |   |  |
|--|----------------------|--|---|--|
| <u>DataStore</u>                               | <u>Resource</u>      | Abstracted of a sufficiently homogeneous storage device providing a storage capacity, managed by a local software component (storage manager), part of a storage service, reachable via zero or more endpoints and having zero or more shares defined on it. A <u>data store</u> refers to a category with summary information on the capacity |   |  |
| Inherited Attribute                            | Type                 | Mult.  | Unit  | Description  |
| <u>CreationTime</u>                            | <u>DateTime</u>      | <u>0..1</u>  |   | <u>Timestamp describing when the entity instance was generated</u>   |
| <u>Validity</u>                                | <u>UInt64</u>        | <u>0..1</u>  | <u>s</u>  | <u>The duration after CreationTime that the information presented in the Entity MAY be considered relevant. After that period has elapsed, the information SHOULD NOT be considered relevant</u> |
| <u>ID</u> [key]                                | <u>URI</u>           | <u>1</u>   |   | <u>A global unique ID</u>  |

7.9 ToComputingService

The ToComputingService class describes a network connection between a Storage Service and a Computing Service which has a level of performance significantly better than the general WAN connection. It is assumed that such a connection applies to the entirety of those Services, i.e. to all Worker Nodes within the Computing Service and all storage within the Storage Service. However, the connection MAY depend on the Access Protocol used to transfer the data.

| Entity                    | Inherits from   | Description  |      |  |
|---------------------------|-----------------|--|------|--|
| <u>ToComputingService</u> | <u>Entity</u>   | Description of the network link quality between a storage service and a computing service and of a potentially dedicated access protocol that the computing service <u>MAY</u> use to access the storage service |      |  |
| Inherited Attribute       | Type            | Mult.  | Unit | Description  |
| <u>CreationTime</u>       | <u>DateTime</u> | <u>0..1</u>  |      | <u>Timestamp describing when the entity instance was generated</u> |

## 8 Relationship to OGF Reference Model

In this section, we describe the integration of the GLUE information model with the OGF Reference Model [\[rm\]](#). The reference model defines the concept of Grid Component. In GLUE, a root concept called Entity is defined. Such a root concept MAY be defined as a specialization of the GridComponent concept, that means that all properties are inherited by the GLUE classes. In Figure 4, we represent this relationship by a UML class diagram.

## 9 Security Considerations

This section considers security implications when using the GLUE 2.0 conceptual model. It follows the advice given in RFC-3552.

As the conceptual model of GLUE 2.0 provides limited scope for embedding security information many of these concerns listed here are delegated to the concrete data models and to the underlying software implementations. Nonetheless, some points are independent of which concrete data model is employed so some discussion is appropriate.

When deploying an information service conforming to the GLUE 2.0 conceptual model, consideration should be given to the points discussed below.

### 9.1 Communication security

The GLUE conceptual model is independent of how information is stored and how that information is exchanged between agents. Because of this, concern for communication security is largely delegated to the underlying concrete data model and software implementations.

Formatted: Heading 2, Justified

Formatted: Justified

#### 9.1.1 Confidentiality

The GLUE conceptual model contains information that MAY be personal or confidential in nature. Contact details and indications of end-user activity MAY fall into this category.

Formatted: Heading 3, Justified

Formatted: Justified

Conforming implementations should identify which components of the data should be considered confidential and appropriate precautions should be in place to safeguard against disclosure to unintended audiences.

#### 9.1.2 Data integrity

The information within GLUE has many potential uses, from operational to accounting. How accurate the information is MAY depend on many factors, including the integrity of software agents that publish data and the transport used to propagate information.

Formatted: Heading 3

Formatted: Justified

The software used to provide an information service MAY cache GLUE information. If so, the caches provide additional points where data integrity MAY be compromised.

#### 9.1.3 Peer Entity authentication

No explicit description of the agents that publish information is included within the GLUE conceptual model. This prevents authentication information from being included within the abstract model.

Formatted: Heading 3

Formatted: Justified

In general, support for peer-entity authentication is delegated to the concrete data model or the underpinning software. In many cases the agents will act on behalf of some AdminDomain; if so, elements of peer entity authentication (e.g., public/private key-pairs) MAY be included using the described schema extension mechanisms provided issues with data integrity are understood.

### 9.2 Non-repudiation

The GLUE conceptual model contains no explicit description of the publishing agents that provide GLUE information. This prevents explicitly support for non-repudiation. In many cases a set of publishing agents will provide information for Services in some AdminDomain. If so, then it is the AdminDomain that asserts the non-repudiation of the data the publishing agents provide.

Formatted: Heading 2

Formatted: Justified

Non-repudiation MAY require information from whoever asserts the non-repudiation of the data; for example, a cryptographic certificate of some AdminDomain. If the publishing agent is identified with an AdminDomain then this information MAY be included using the schema extension mechanisms of the AdminDomain (via OtherInfo or Extension). It is also possible for this information to be included in fields specific to the concrete data model or it MAY be provided outside of the GLUE conceptual model.

In addition, information MAY be published with corresponding non-repudiation information, such as a cryptographic signature. Signatures MAY be included using schema extensions (OtherInfo or Extension) or MAY be included in fields specific to the concrete data model.

### 9.3 System security

Formatted: Heading 2

Formatted: Justified

The GLUE conceptual model intended use is to provide an abstract view of a grid system. There are many processes that MAY make use of this information, each MAY depend on the GLUE conceptual model to undertake work.

#### 9.3.1 Unauthorized usage

Formatted: Heading 3

Formatted: Justified

The GLUE conceptual model has no explicit description of end-users of the schema information and no explicit description of authorized usage. In general, is assumed that any authorization controls for access to the GLUE information is provided by specific concrete bindings and software implementation.

It MAY be possible to identify a UserDomain with those agents authorised to use GLUE information and embed authorization information using described schema extension mechanisms, provided issues with data integrity are understood.

#### 9.3.2 Inappropriate Usage

Formatted: Heading 3

Formatted: Justified

The GLUE conceptual model provides no mechanism for describing appropriate usage and does not include a data-processing model, so providing a description of inappropriate usage is considered out-of-scope.

Individual grids MAY describe what they consider appropriate usage of GLUE information and implement appropriate procedures to ensure this policy is enacted.

### 9.4 Specific attacks

Formatted: Heading 2

Formatted: Justified

RFC-3552 describes several specific attacks that MUST be considered. These are detailed below.

#### 9.4.1 Eavesdropping

Formatted: Heading 3

Formatted: Justified

Some information described in the GLUE conceptual model MAY be sensitive in nature; this MAY include contact details and descriptions of user activity. Appropriate care should be taken to prevent unintended access or disclosure to an unintended audience.

#### 9.4.2 Replay

Formatted: Heading 3

Formatted: Justified

Grid operations MAY depend on information provided in the GLUE conceptual model.

If a system implementing the GLUE 2.0 conceptual model is susceptible to a replay attack then it is possible for part (possibly all) of the information in the conceptual model to be reverted to some previous state as seen by some (possible all) end users. Please note that this is a specific case of the more general modification attack.

A replay attack MAY result in disrupted service. If security attributes, such as authorization, are embedded within the GLUE conceptual model then a replay attack MAY result in inappropriate access to data.

Underlying concrete models and software implementations should prevent replay attacks.

#### 9.4.3 Message insertion

The ability to insert information is key to providing accurate information. However, inserting incorrect information MAY have a detrimental effect to the running systems; for example, there are attributes in the conceptual model that accept multiple values. If incorrect values are included, the systems MAY suffer.

Many aspects of GLUE provide service discovery. Inserting false information would allow unauthorised services to publish their presence and attract activity. This MAY be used as a basis for further attacks.

Underlying concrete models and software implementations should ensure that any agent's ability to insert information is limited and appropriate.

#### 9.4.4 Deletion

The ability to delete information from an information service could interfere with normal operations; for example, if Services are removed then activity that would use those services MAY be affected; if AdminDomains are removed then normal operation procedures MAY be impossible; if security components are removed (such as X509 certificates) then facilities such as non-repudiation MAY become ineffectual.

Underlying concrete models and implementing software should ensure that any ability of an agent to delete information is limited and appropriate.

#### 9.4.5 Modification

The ability for an agent to modify information stored in an information service is key to providing accurate information. However, concrete data models and software implementation should place limits such that the agents' ability to modify information is controlled and appropriate.

#### 9.4.6 Man-in-the-middle

For a system implementing the GLUE conceptual model, a successful man-in-the-middle attack MAY lead to arbitrary modification of data (see 9.4.5). It MAY also allow deleting existing data (see 9.4.4) or adding additional data (see 9.4.3). This MAY have severe influence on the systems based on GLUE information.

Underlying concrete models and implementing software should understand the risk from man-in-the-middle attacks and provide appropriate security against them.

#### 9.4.7 Denial of service attacks

A Denial of Service attack is one that attempts to prevent normal operation of systems. Perhaps, the most obvious is to prevent or corrupt the flow of information.

Formatted: Heading 3

Formatted: Justified

Formatted: Heading 3

Formatted: Justified

Systems using the GLUE conceptual model should understand the consequences of a partial or complete lack of information. Appropriate measures should be taken to ensure the systems continue to run to the extent possible.

Please refer to RFC 3552 (<http://www.ietf.org/rfc/rfc3552.txt>) for guidance on writing a security considerations section. This section is required in all documents, and should not just say "there are no security considerations." Quoting from the RFC: ¶

¶  
 "Most people speak of security as if it were a single monolithic property of a protocol or system, however, upon reflection, one realizes that it is clearly not true. Rather, security is a series of related but somewhat independent properties. Not all of these properties are required for every application.¶

¶  
 We can loosely divide security goals into those related to protecting communications (COMMUNICATION SECURITY, also known as COMSEC) and those relating to protecting systems (ADMINISTRATIVE SECURITY or SYSTEM SECURITY). Since communications are carried out by systems and access to systems is through communications channels, these goals obviously interlock, but they can also be independently provided."¶

## Place-holder values for unknown data

Whilst people endeavor to provide accurate information, there **MAY** be situations where specific GLUE attributes **MAY** be assigned place-holder (or dummy) values. These place-holder values carry some additional semantic meaning; specifically, that the correct value is currently unknown and the presented value should be ignored. This appendix describes a set of such place-holder values.

Some attributes within the GLUE schema are required whilst others are optional. If the attribute is optional and the corresponding information is unavailable, the information provider **MUST** either publish a place-holder or not to publish the attribute. If the attribute is required, then the information **MUST** either publish a place-holder value or refrain from publishing the GLUE object.

If a place-holder value is published, it **MUST** conform to the scheme described in this appendix. This is to increase the likelihood that software will understand the nature of the information it receives.

This appendix describes place-holder values that have been chosen so they are obvious "wrong" to humans, unlikely to occur under normal operation and valid within the attribute type. This also allows for detection of failing information provider components.

### 16.1 Use cases

There are two principle use-cases for place-holder values, although others **MAY** exist.

Scenario 1. a static value has no good default value and has not been configured for a particular site.

Some provisions for GLUE Schema provide templates. These templates **MAY** contain attributes that have no good default value; for example, supplying the correct value **MAY** require site-specific knowledge. Whilst it is expected that these attributes be configured, it is possible that this does not happen, so exposing the attributes' default values.

Scenario 2. information provider is unable to obtain a dynamic value.

A dynamic value is provided by an information provider by querying the underlying grid resources. This query will use a number of ancillary resources (e.g., DNS, network hardware) that might fail; the grid services might also fail. If an attribute is required and the current value is unobtainable, a place-holder value **MUST** be used.

### 16.2 Place-holder values

This section describes a number of values that **MAY** be represented within a given address space (e.g., Strings/UTF-8, Integers, FQDNs, IPv4 address space). Each of the different types are introduced along with the place-holder value and a brief discussion on usage, rationale and any other considerations.

### 16.3 Extended booleans

**The reserved value "undefined" SHOULD be used. The way to express that no value is published MUST be defined in the documents defining the realization to concrete data models (e.g., [glue-real]).**

**Deleted:** may

**Deleted:** may

**Deleted:** must

**Formatted:** Left

**Deleted:** can

**Formatted:** Heading 2, Left

**Formatted:** nobreak, Left

**Formatted:** Left

**16.4** Simple strings

(ASCII/UTF-8) should use "UNDEFINEDVALUE" or should start "UNDEFINEDVALUE:"

Upper-case letters make it easier to spot and a single word avoids any white-space issues.

A short error message **MAY** be incorporated into the message by appending the message after the colon.

Examples:

UNDEFINEDVALUE

UNDEFINEDVALUE: unable to contact torque daemon.

Using UNDEFINEDVALUE is a default option for strings that have no widely-known structure. If a value is of a more restrictive sub-type (e.g., FQDNs, FQANs, URIs) described below, then the rules for more restrictive form **MUST** be used.

**Formatted:** Bullets and Numbering

**Deleted:** can

**Deleted:** must

**16.5** Fully qualified domain names

They **MUST** use a hostname ending either "example.org" for scenario 1, or "invalid" for scenario 2.

RFC 2606 defines two second-level domains: "example.org" and "example.com". These domains have the advantage of ending with a recognisable TLD, so are recognisable as a DNS name.

Default configuration (scenario 1, above) **MUST** use DNS names that end "example.org"

RFC 2606 also reserves the "invalid" Top-Level-Domain (TLD) as always invalid and clearly so. For dynamic information gathering, a value ending "invalid" **MUST** be used.

In both cases, additional information **MAY** be included by specifying a prefix to "example.org" or "invalid". This **MAY** be used to specify the class of machine that should be present. For dynamic information, if the class of machine is not published then the FQDN "unknown.invalid" **MUST** be used.

Examples:

www.example.org

your-CE.example.org

unknown.invalid

site-local-BDII.invalid

**Formatted:** Heading 2, Left

**Formatted:** Bullets and Numbering

**Deleted:** must

**Deleted:** must

**Deleted:** must

**Deleted:** may

**Deleted:** may

**Deleted:** must

**16.6** IPv4 address

It **MUST** use 192.0.2.250

There are several portions of IPv4 addresses that should not appear on a network, but none that are reserved for documentation or to specify a non-existent address. Using any address leads to the risk of side-effects, should this value be used.

The best option is an IP address from the 192.0.2.0/24 subnet. This subnet is defined in RFC 3330 as "TEST-NET" for use in documentation and example code. For consistency, the value 192.0.2.250 **MUST** be used.

**Formatted:** Heading 2

**Formatted:** Bullets and Numbering

**Deleted:** must

**Deleted:** must

## 16.7 IPv6 addr

It **MUST** use 2001:DB8::FFFF

There is no documented undefined IPv6 address. RFC 3849 reserves the address prefix 2001:DB8::/32 for documentation. For consistency, the address 2001:DB8::FFFF **MUST** be used.

**Formatted:** Heading 2, Left

**Formatted:** Bullets and Numbering

**Deleted:** must

**Deleted:** must

## 16.8 Integers

It **MUST** use "all nines"

For uint32/int32 this is 999,999,999

For uint64/int64 this is 999,999,999,999,999,999

For integers, all numbers expressible within the encoding (int32/uint32/etc.) are valid so there is no safe choice.

If an unsigned integer is encoded as a signed integer, it is possible to use negative numbers safely. However, these numbers will be unrepresentable if the number is stored as an unsigned integer. For this reason a negative number place-holder **MUST** not be used.

**Formatted:** Heading 2

**Formatted:** Bullets and Numbering

**Deleted:** must

**Deleted:** must

The number was chosen for three reasons. First, attribute scales are often chosen to reduce the likelihood of overflow: numbers towards MAXINT (the large number representable in an integer domain) are less likely to appear. Second, repeated numbers stand out more clearly to humans. Finally, the statistical frequency of measured values often follows Benford's law, which indicates that numbers starting with "1" occur far more frequently than those starting with "9" (about six times more likely). For these reasons, information providers **MUST** use all-nines to indicate a place-holder.

**Deleted:** must

## 16.9 File path

It **MUST** start either "/UNDEFINEDPATH" or "\UNDEFINEDPATH".

As with the simple string, a single upper-case word is recommended. The initial slash indicates that the value is a path. Implementations **MUST** use whichever slash is most appropriate for the underlying system (Unix-like systems use a forward-slash). Software should accept either value as an unknown-value place-holder.

Additional information **MAY** be encoded as data beyond the initial UNDEFINEDPATH, separated by the same slash as started the value. Additional comments should not use any of the following characters: \ [ ] ; = " : | , \* .

**Formatted:** Heading 2

**Formatted:** Bullets and Numbering

**Deleted:** must

**Deleted:** must

**Deleted:** can

Examples:

/UNDEFINEDPATH

\UNDEFINEDPATH

/UNDEFINEDPATH/Path to storage area

/UNDEFINEDPATH/Broker unavailable

## 16.10 Email addresses

It **MUST** use an undefined FQDN for the domain.

RFC 2822 defines emails addresses to have the form: <local-part> '@' <domain>

**Formatted:** Heading 2

**Formatted:** Bullets and Numbering

**Deleted:** must

example@ggf.org

The <domain> **MUST** be an undefined FQDN; see above for a complete description. For email addresses, information providers should use "example.org" for scenario 1. and "unknown.invalid" for scenario 2.

**Deleted:** must

The <local-part> **MAY** be used to encode a small amount of additional information; for example, it **MAY** indicate the class of user to whom the email address should be delivered. If no such information is to be encoded the value "user" **MUST** be used.

**Deleted:** may

**Deleted:** may

**Deleted:** must

**Formatted:** French (France)

Examples:

user@example.org  
user@unknown.invalid  
site-local-contact@example.org  
local-admin@example.org

## 16.11 Uniform Resource Identifier (URI)

**Formatted:** Heading 2

It is schema-specific

**Formatted:** Bullets and Numbering

**Formatted:** French (France)

RFC 3986 defines URIs as a "federated and extensible naming system." All URIs start with a schema-name part (e.g., "http") and no schema-name has been reserved for undefined or documenting example values.

For any given URI schema ("http", for example), it **MAY** be possible to define a **place-holder** value within that name-space. If a GLUE value has only one valid schema, the undefined value **MUST** be taken from that schema. If several schemata are possible, one **MUST** be chosen from the available options. This should be the most commonly used.

**Deleted:** may

**Deleted:** n

**Deleted:** unknown

**Deleted:** must

**Deleted:** must

**Deleted:** must

Take care with the URI encoding. All place-holder URI values **MUST** be valid URIs. If additional information is included, it **MUST** be encoded so the resulting URI is valid.

**Deleted:** may

For schemata that **MAY** include a FQDN (e.g., a reference to an Internet host), an undefined URI **MUST** use an undefined FQDN; see above for details on undefined FQDNs.

**Deleted:** must

URI schemata that reference a remote file (e.g., "http", "ftp", "https"), additional information **MAY** be included as the path. The FQDN indicates that the value is a place-holder, indicating an **place-holder** value, so information providers should not specify "UNDEFINEDPATH".

**Deleted:** may

**Deleted:** unknown

For "file" URIs, the path part **MUST** identify the value as unknown and **MUST** use the forward-slash variant; see above for details on undefined paths.

**Deleted:** must

**Deleted:** must

For "mailto" URIs [RFC 2368] encapsulates valid email addresses with additional information (such as email headers and message body). Place-holder mailto URIs **MUST** use an unknown email address (see above). Any additional information **MUST** be included in the email body.

**Deleted:** must

There **MAY** be other schemata in use that are not explicitly covered in this section. A place-holder value should be agreed upon within whichever domain such schemata are used. This place-holder value should be in the spirit of the place-holder values described so far.

**Deleted:** may

Examples:

http://www.example.org/  
httpg://your-CE.example.org/path/to/end-point  
httpg://unknown.invalid/User%20certificate%20has%20expired  
mailto:site-admin@example.org  
mailto:user@maildomain.invalid?body=Problem%20connecting%20to%20WLMS  
file:///UNDEFINEDPATH

file:///UNDEFINEDPATH/path%20to%20some%20directory

## 16.12 X.509 Distinguished Names

It **MUST** start `O=Grid,CN=UNDEFINEDUSER`

X.509 uses a X.509 namespace, represented as several Relative Domain-Names (RDNs) concatenated by **commas** (we refer to syntax defined in IETF RFC 4514). The final RDN is usually a single common name (CN), although multiple CNs are allowed.

Unknown DN values **MUST** have at least two entries: an initial `O=Grid` followed immediately by `CN=UNDEFINEDUSER`.

Additional information **MAY** be encoded using extra CN entries. These **MUST** come after `CN=UNDEFINEDUSER`.

Examples:

`O=Grid,CN=UNDEFINEDUSER`

`O=Grid,CN=UNDEFINEDUSER/CN=Your Grid certificate DN here`

`O=Grid,CN=UNDEFINEDUSER/CN=Cannot access SE`

## 16.13 Fully Qualified Attribute Name (FQAN)

It **MUST** use a VO of "vo.example.org" (for scenario 1.) or "unknown.invalid" (for scenario 2).

The "VOMS Credential Format" document,

<http://edg-wp2.web.cern.ch/edg-wp2/security/voms/edg-voms-credential.pdf>

states that FQANs **MUST** have the form:

`/VO[/group[/subgroup(s)]][/Role=role][[/Capability=cap]`

Where VO is a well-formed FQDN. Unlike FQDNs, VO names **MUST** be lower-case. The place-holder value for FQAN is derived from the place-holder FQDN (see Section 16.5). It **MUST** have no subgroup(s) or Capability specified.

Any additional information **MUST** be encoded within a single Role name. Care should be taken that only valid characters (A-Z, a-z, 0-9 and dash) are included.

Examples:

`/vo.example.org`

`/vo.example.org/Role=Replace-this-example-with-your-FQAN`

`/unknown.invalid`

`/unknown.invalid/Role=Unable-to-contact-CE-Error-42`

## 16.14 Geographic locations

It **MUST** use longitude 0 degrees, latitude 0 degrees.

Meridians of longitude are taken from (-180,180] degrees, whilst parallels of latitude are taken from [-90,90] degrees. For a place-holder value to be a valid location, it **MUST** also be taken from these ranges.

example@ggf.org

By a happy coincidence, the (0,0) location is within the Atlantic Ocean, some 380 miles (611 kilometers) south of the nearest country (Ghana). Since this location is unlikely to be used and repeated numbers are easier for humans to spot, (0,0) **MUST** be used to specify an place-holder location.

**Deleted:** must

**Formatted:** Bullets and  
Numbering

## 17 Data Types

This section contains the definition of **attribute** types defined within this model. The enumeration types **MAY** be either closed or open. For properties which type defines a closed enumeration, one of the defined values **MUST** be chosen; any other value is not valid. For properties which type defines an open enumeration, one of the defined values **MAY** be chosen, nevertheless any other value compatible with the string type and with the recommended syntax is allowed.

**Deleted:** property

**Deleted:** can

The enumeration values **MUST** be lower-case.

### 17.1 ExtendedBoolean\_t

#### Closed enumeration

| Value     | Description                  |
|-----------|------------------------------|
| False     | boolean false                |
| True      | boolean true                 |
| undefined | the value cannot be measured |

**Deleted:** ¶

**Formatted:** Justified

**Formatted:** Heading 2

### 17.2 LocalID\_t

The base type is the string with the following restrictions:

- first char in a-zA-Z
- following characters in [\w\-\.\:]\n
  - \w = [a-zA-Z\_0-9]

**Formatted:** Bullets and Numbering

### 17.3 ContactType\_t

#### Open enumeration

| Value       | Description                                      |
|-------------|--|
| general     | Contact for persons to ask about general issues  |
| security    | Contact for persons responsible for the security |
| Sysadmin    | Contact for the system administration            |
| usersupport | Contact for the user support                     |

**Formatted:** Bullets and Numbering

### 17.4 PolicyScheme\_t

#### Open enumeration

| Value | Description                  |
|-------|------------------------------|
| basic | The basic scheme             |
| gacl  | GridSite Access Control List |

A policy scheme is defined by a syntax for rules and by a matching algorithm defining how a string **MAY** be matched against the published rules. For the *basic* policy scheme, the following syntax **MUST** be used (defined in EBNF form [EBNF]):

- BASIC RULE ::= ( DN\_NAME | VO\_NAME | 'ALL' )
- DN RULE ::= 'dn:' DN\_NAME
- VO RULE ::= 'vo:' [a-zA-Z0-9- \.]+
- DN NAME ::=

As a matching algorithm, the basic scheme adopts the exact match (if at least one rule provides an exact match or the rule 'ALL' is present, then the subject is authorized to be mapped into the related share). More complex policy schemes **SHOULD** be defined in profile documents.

**Deleted:** security ... [41]

**Formatted:** Bullets and Numbering

**Deleted:** Basic

**Deleted:** G

**Deleted:**

**Formatted:** Bullets and Numbering

**Formatted:** Italian (Italy)

**Deleted:** <#>¶  
 basic rule ::= ['DENY:']  
 (DN\_RULE | FQAN\_RULE |  
 'ALL')¶  
 <#>DN\_RULE ::= 'dn:'  
 DN\_NAME ¶  
 <#>FQAN\_RULE ::= 'fqan:'  
 VO\_NAME ( '/' GROUP\_NAME  
 ) \* ( '/' Role= ' ROLE\_NAME ) ? ¶  
 <#>VO\_NAME ::= [a-zA-Z0-9-  
 \.]+¶  
 <#>GROUP\_NAME ::=  
 VO\_NAME ¶  
 <#>ROLE\_NAME ::=  
 VO\_NAME ¶

Examples of policies expressed using the basic syntax are:

- `dn:/C=XX/O=YYYY/OU=Personal Certificate/L=ZZZZ/CN=NAME SURNAME`
  - matches the user proving to have a certificate identified by this DN
- `vo:/vo_a`
  - matches all the users proving to be part of the vo\_a

## 17.5 DN\_t

Distinguished Name as defined by RFC 4514 (<http://www.rfc-editor.org/rfc/rfc4514.txt>).

X.509 uses a X.500 namespace, represented as several Relative Domain-Names (RDNs) concatenated by forward-slashes. The final RDN is usually a single common name (CN), although multiple CNs are allowed.

## 17.6 Capability\_t

List of values initially drafted from [omii-jra2-djra2.1, OGF-GFD80]. Open enumeration.

| Value   | Description  |
|---|--|
| <a href="#">data.access.flatfiles</a>                     | <a href="#">capacity of providing access to a flat file</a>  |
| <a href="#">data.access.relational</a>                    | <a href="#">capacity of providing access to a relational data source</a>   |
| <a href="#">data.access.xml</a>                           | <a href="#">capacity of providing access to an XML data source</a>   |
| <a href="#">data.management.replica</a>                   | <a href="#">capacity of managing the creation of file replicas upon request</a>  |
| <a href="#">data.management.storage</a>                   | <a href="#">capacity of managing a storage resource, from simple systems like disk-servers to complex hierarchical systems</a>   |
| <a href="#">data.management.transfer</a>                  | <a href="#">capacity of managing a transfer of files from the start to the completion</a>  |
| <a href="#">data.naming.resolver</a>                      | <a href="#">capacity of resolving one name to another (for example, search the associated abstract name to a certain human-oriented name)</a>  |
| <a href="#">data.naming.scheme</a>                        | <a href="#">capacity of attaching names to data resources. (To evaluate if it should moved to the main category infrastructure instead of data). In OGSA, a three-level naming scheme is defined: (1) human-oriented name, (2) abstract name and (3) address</a> |
| <a href="#">data.transfer</a>                             | <a href="#">capacity of moving a file from one network location to another. It refers to the actual transfer (e.g., as performed by protocols like FTP, GridFTP, or HTTP)</a>  |
| <a href="#">executionmanagement.candidatesetgenerator</a> | <a href="#">capacity of determining the set of resources in which a unit of work MAY execute</a>   |
| <a href="#">executionmanagement.dynamicvmdeploy</a>       | <a href="#">capacity of dynamically deploying a virtual machine image in a worker node</a>   |
| <a href="#">executionmanagement.executionandplanning</a>  | <a href="#">capacity of building schedules for jobs, that is, the capability of defining mappings between services and resources, possibly with time constraints</a>   |
| <a href="#">executionmanagement.jobdescription</a>        | <a href="#">capacity of letting users be able to describe a job submission request based on a machine-processable language</a>   |
| <a href="#">executionmanagement.jobexecution</a>          | <a href="#">capacity of executing a job or set of jobs.</a>  |
| <a href="#">executionmanagement.jobmanager</a>            | <a href="#">capacity of managing the execution of a job or set of jobs from start to finish</a>  |
| <a href="#">executionmanagement.reservation</a>           | <a href="#">capacity of managing reservation of resources for future usage</a>   |
| <a href="#">information.discovery</a>                     | <a href="#">capacity of locating unknown resources or services, possibly satisfying a set of requirements</a>  |
| <a href="#">information.logging</a>                       | <a href="#">capacity of recording data, often chronologically</a>  |
| <a href="#">information.model</a>                         | <a href="#">capacity of modelling resources based on a community accepted definition</a>   |
| <a href="#">information.monitoring</a>                    | <a href="#">capacity of periodically observing measurements, transform them and make available to users or other applications</a>  |
| <a href="#">information.provenance</a>                    | <a href="#">capacity of providing long-term storage of information related to Grid activity and to let this information be accessed by users or other applications.</a>  |
| <a href="#">security.accounting</a>                       | <a href="#">capacity of systematically recording, reporting, and analyzing the usage of resources</a>  |
| <a href="#">security.attributeauthority</a>               | <a href="#">capacity of associating a user with a set of attributes in a trusted manner to a relying party, by way of digitally signed assertions</a>  |
| <a href="#">security.authentication</a>                   | <a href="#">capacity of providing authentication mechanisms for Grid users machine and services</a>  |

### 17.29 ComputingActivityState\_t

For the values of this type, we RECOMMEND the following syntax:

- namespace:state
- namespace:state:substate

**Formatted:** Bullets and Numbering

Open enumeration:

| Value                          | Description   |
|--------------------------------|---|
| <a href="#">bes:failed</a>     | <a href="#">(a terminal state): the activity has failed due to some system error/failure event, such as failure of a computational resource that the activity was running on</a>  |
| <a href="#">bes:finished</a>   | <a href="#">(a terminal state): the activity has terminated successfully. Successful termination implies that the activity exited of its own accord rather than due to some failure in the BES or of the computational resources on which the activity was running. Note that a successfully terminating activity MAY nevertheless return an error code as its return value</a> |
| <a href="#">bes:pending</a>    | <a href="#">the service has created a record for an activity but not yet instantiated it on a suitable computational resource or enabled it to start execution on such a resource</a>   |
| <a href="#">bes:running</a>    | <a href="#">the activity is executing on some computational resource</a>  |
| <a href="#">bes:terminated</a> | <a href="#">(a terminal state): the client – which might be some system administrator</a>   |

(and hence not necessarily the client who originated the request to create the activity) – has issued a `TerminateActivity` request

**Deleted:** bes:pending ... [64]

For more information on the BES state model, see [BES].

This **attribute** type is an open enumeration. Examples of additional values are:

**Deleted:** property

- a middleware provider is using its own state model defined before the BES specification:
  - NorduGrid defines the state *accepting* which **MAY** be represented as (see [ng-schema], page 28):
    - nordugrid:accepting
  - gLite WMS defines the state *scheduled* which **MAY** be represented as:
    - glite-wms:scheduled
  - gLite CREAM defines the state *registered* which **MAY** be represented as:
    - glite-cream:registered
    - (see <https://edms.cern.ch/document/595770>)
- a middleware provider defined an extension of BES state model which is not part of an official OGF specification
  - NorduGrid defined an extension the bes:pending by adding two substates:
    - nordugrid-bes:pending:accepting
    - nordugrid-bes:pending:accepted

### 17.32 AccessLatency\_t

Closed enumeration:

**Formatted:** Bullets and Numbering

**Formatted:** nobreak

| Value    | Description  |
|----------|--|
| nearline | A file MAY have its only copies in a "nearly online" component of the storage system, typically a fully automated tape robot, but also a remote storage system could fit this qualification. Such a facility will need an unspecified amount of time to make a copy of the file available on the disk component of the container under consideration. When a file is not in use, its disk copies MAY be removed. Hence the system cannot guarantee that a file will be |

|                |   |
|----------------|---|
|                | <u>immediately available on disk</u>  |
| <u>offline</u> | <u>A file MAY have its only copies in an offline component of the storage system, for example a tape library that is not connected to an automated tape robot. Hence an operator intervention MAY be needed to make a copy of a file available that has a lower latency</u> |
| <u>online</u>  | <u>Files are always on disk, hence cannot have their latency improved</u>   |

**Deleted:** online ... [66]

### 17.33 RetentionPolicy\_t

Open enumeration:

| Value            | Description  |
|------------------|--|
| <u>custodial</u> | <u>Low probability of loss</u>   |
| <u>output</u>    | <u>An intermediate level and is appropriate for data which MAY be replaced by lengthy or effort-full processes</u>   |
| <u>replica</u>   | <u>The highest probability of loss, but is appropriate for data for which a certain amount of loss MAY be tolerated, in particular when other copies MAY be accessed in a timely fashion</u> |

**Deleted:** custodial ... [67]

### 17.34 ExpirationMode\_t

Closed enumeration:

| Value                     | Description   |
|---------------------------|---|
| <u>neverexpire</u>        | <u>Support for files with infinite lifetime: they MAY only be removed by authorized clients, not by the storage system itself</u>   |
| <u>releasewhenexpired</u> | <u>Support for files that have finite lifetimes and on expiration will be removed by the storage system</u>   |
| <u>warnwhenexpired</u>    | <u>Support for files that have finite lifetimes, but on expiration cannot be removed by the storage system itself. The data content of an expired file MAY be deleted if it MAY be recovered from an archive. New store operations MAY fail for certain clients until (some of the) expired files have either been removed by authorized clients, or have had their lifetimes increased</u> |

**Deleted:** neverexpire ... [68]

**Page 64: [42] Deleted Sergio Andreozzi 12/3/2008 3:48:00 PM**

|                             |  |  |  |  |
|-----------------------------|--|--|--|--|
| security.authentication     | Capacity of providing authentication mechanisms for Grid users machine and services  |  |  |  |
| security.credentialstorage  | Capacity of providing an online credential repository that allows users to securely obtain credentials when and where needed   |  |  |  |
| security.delegation         | capacity for a user to give a service the authority to undertake specific activities or decisions on its behalf  |  |  |  |
| security.authorization      | capacity of handling authorization aspects, making authorization decisions about the subject and the requested mode of access based upon combining information from a number of distinct sources |  |  |  |
| security.identitymapping    | capacity of mapping Grid-level credentials to local level credentials (e.g., mapping a user X.509 certificate into a UNIX account).  |  |  |  |
| security.attributeauthority | capacity of associating a user with a set of attributes in a trusted manner  |  |  |  |

|   |  |
|---|--|
|   | to a relying party, by way of digitally signed assertions  |
| security.accounting                       | capacity of systematically recording, reporting, and analyzing the usage of resources  |
| data.transfer                             | capacity of moving a file from one network location to another. It refers to the actual transfer (e.g., as performed by protocols like FTP, GridFTP, or HTTP)  |
| data.management.transfer                  | capacity of managing a transfer of files from the start to the completion  |
| data.management.replica                   | capacity of managing the creation of file replicas upon request  |
| data.management.storage                   | capacity of managing a storage resource, from simple systems like disk-servers to complex hierarchical systems   |
| data.naming.resolver                      | capacity of resolving one name to another (for example, search the associated abstract name to a certain human-oriented name)  |
| data.naming.scheme                        | capacity of attaching names to data resources. (To evaluate if it should moved to the main category infrastructure instead of data). In OGSA, a three-level naming scheme is defined: (1) human-oriented name, (2) abstract name and (3) address |
| data.access.relational                    | capacity of providing access to a relational data source   |
| data.access.xml                           | capacity of providing access to an XML data source   |
| data.access.flatfiles                     | capacity of providing access to a flat file  |
| information.model                         | capacity of modelling resources based on a community accepted definition   |
| information.discovery                     | capacity of locating unknown resources or services, possibly satisfying a set of requirements  |
| information.logging                       | capacity of recording data, often chronologically  |
| information.monitoring                    | capacity of periodically observing measurements, transform them and make available to users or other applications  |
| information.provenance                    | capacity of providing long-term storage of information related to Grid activity and to let this information be accessed by users or other applications.  |
| executionmanagement.jobexecution          | capacity of executing a job or set of jobs.  |
| executionmanagement.jobdescription        | capacity of letting users be able to describe a job submission request based on a machine-processable language   |
| executionmanagement.jobmanager            | capacity of managing the execution of a job or set of jobs from start to finish  |
| executionmanagement.executionandplanning  | capacity of building schedules for jobs, that is, the capability of defining mappings between services and resources, possibly with time constraints   |
| executionmanagement.candidatesetgenerator | capacity of determining the set of resources on which a nit of workcan execute   |
| executionmanagement.reservation           | capacity of managing reservation of resources for future usage   |
| executionmanagement.dynamicvmdeploy       | capacity of dynamically deploying a virtual machine image in a worker node   |

|----------------|---|
| bes:pending    | the service has created a record for an activity but not yet instantiated it on a suitable computational resource or enabled it to start execution on such a resource   |
| bes:running    | the activity is executing on some computational resource  |
| bes:finished   | (a terminal state): the activity has terminated successfully. Successful termination implies that the activity exited of its own accord rather than due to some failure in the BES or of the computational resources on which the activity was running. Note that a successfully terminating activity may nevertheless return an error code as its return value |
| bes:failed     | (a terminal state): the activity has failed due to some system error/failure event, such as failure of a computational resource that the activity was running on  |
| bes:terminated | (a terminal state): the client – which might be some system administrator (and hence not necessarily the client who originated the request to create the activity) – has issued a TerminateActivity request   |

|          |  |
|----------|--|
| online   | Files are always on disk, hence cannot have their latency improved   |
| nearline | A file may have its only copies in a "nearly online" component of the storage system, typically a fully automated tape robot, but also a remote storage system could fit this qualification. Such a facility will need an unspecified amount of time to make a copy of the file available on the disk component of the container under consideration. When a file is not in use, its disk copies may be removed. Hence the system cannot guarantee that a file will be immediately available on disk |
| offline  | A file may have its only copies in an offline component of the storage system, for example a tape library that is not connected to an automated tape robot. Hence an operator intervention may be needed to make a copy of a file available that has a lower latency   |
